Chapter 1

Introduction

CVODE is part of a software family called SUNDIALS: SUite of Nonlinear and DIfferential/ALgebraic equation Solvers [25]. This suite consists of CVODE, ARKODE, KINSOL, and IDA, and variants of these with sensitivity analysis capabilities.

1.1 Historical Background

FORTRAN solvers for ODE initial value problems are widespread and heavily used. Two solvers that have been written at LLNL in the past are VODE [5] and VODPK [8]. VODE is a general purpose solver that includes methods for both stiff and nonstiff systems, and in the stiff case uses direct methods (full or banded) for the solution of the linear systems that arise at each implicit step. Externally, VODE is very similar to the well known solver LSODE [33]. VODPK is a variant of VODE that uses a preconditioned Krylov (iterative) method, namely GMRES, for the solution of the linear systems. VODPK is a powerful tool for large stiff systems because it combines established methods for stiff integration, nonlinear iteration, and Krylov (linear) iteration with a problem-specific treatment of the dominant source of stiffness, in the form of the user-supplied preconditioner matrix [6]. The capabilities of both VODE and VODPK have been combined in the C-language package CVODE [13].

At present, CVODE may utilize a variety of Krylov methods provided in SUNDIALS that can be used in conjuction with Newton iteration: these include the GMRES (Generalized Minimal RESidual) [36], FGMRES (Flexible Generalized Minimum RESidual) [35], Bi-CGStab (Bi-Conjugate Gradient Stabilized) [37], TFQMR (Transpose-Free Quasi-Minimal Residual) [19], and PCG (Preconditioned Conjugate Gradient) [20] linear iterative methods. As Krylov methods, these require almost no matrix storage for solving the Newton equations as compared to direct methods. However, the algorithms allow for a user-supplied preconditioner matrix, and for most problems preconditioning is essential for an efficient solution. For very large stiff ODE systems, the Krylov methods are preferable over direct linear solver methods, and are often the only feasible choice. Among the Krylov methods in SUNDIALS, we recommend GMRES as the best overall choice. However, users are encouraged to compare all options, especially if encountering convergence failures with GMRES. Bi-CGStab and TFQMR have an advantage in storage requirements, in that the number of workspace vectors they require is fixed, while that number for GMRES depends on the desired Krylov subspace size. FGMRES has an advantage in that it is designed to support preconditioners that vary between iterations (e.g. iterative methods). PCG exhibits rapid convergence and minimal workspace vectors, but only works for symmetric linear systems.

In the process of translating the VODE and VODPK algorithms into C, the overall CVODE organization has been changed considerably. One key feature of the CVODE organization is that the linear system solvers comprise a layer of code modules that is separated from the integration algorithm, allowing for easy modification and expansion of the linear solver array. A second key feature is a separate module devoted to vector operations; this facilitated the extension to multiprosessor environments with minimal impacts on the rest of the solver, resulting in PVODE [11], the parallel variant of CVODE.

2 Introduction

Around 2002, the functionality of CVODE and PVODE were combined into one single code, simply called CVODE. Development of this version of CVODE was concurrent with a redesign of the vector operations module across the SUNDIALS suite. The key feature of the NVECTOR module is that it is written in terms of abstract vector operations with the actual vector kernels attached by a particular implementation (such as serial or parallel) of NVECTOR. This allows writing the SUNDIALS solvers in a manner independent of the actual NVECTOR implementation (which can be user-supplied), as well as allowing more than one NVECTOR module linked into an executable file. SUNDIALS (and thus CVODE) is supplied with six different NVECTOR implementations: serial, MPI-parallel, and both OpenMP and Pthreads thread-parallel NVECTOR implementations, a Hypre parallel implementation, and a PETSc implementation.

There are several motivations for choosing the C language for CVODE. First, a general movement away from FORTRAN and toward C in scientific computing was apparent. Second, the pointer, structure, and dynamic memory allocation features in C are extremely useful in software of this complexity, with the great variety of method options offered. Finally, we prefer C over C++ for CVODE because of the wider availability of C compilers, the potentially greater efficiency of C, and the greater ease of interfacing the solver to applications written in extended FORTRAN.

1.2 Changes from previous versions

Changes in v4.0.0-dev.1

An API for encapsulating the nonlinear solvers used in SUNDIALS implicit integrators has been introduced. The goal of this API is to ease the introduction of new nonlinear solver options in SUNDIALS integrators and allow for external or user-supplied nonlinear solvers. The SUNNONLINSOL API and provided SUNNONLINSOL modules are described in Chapter 9 and follow the same object oriented design and implementation used by the NVECTOR, SUNMATRIX, and SUNLINSOL modules.

SUNNONLINSOL modules are intended to solve nonlinear systems formulated as either a rootfinding problem F(y) = 0 or a fixed-point problem G(y) = y. Currently two sunnonlinsol implementations are provided, sunnonlinsol_newton and sunnonlinsol_fixed-point. These replicate the previous integrator specific implementations of a Newton iteration and a fixed-point iteration (previously referred to as a functional iteration), respectively. Additionally, the fixed-point iteration can use Anderson's method to accelerate convergence. Example programs using each of these nonlinear solver modules in a standalone manner have been added and all CVODE example programs have been updated to use generic SUNNONLINSOL modules.

With the introduction of SUNNONLINSOL modules, the input parameter iter to CVodeCreate has been removed as well as the constants CV_NEWTON and CV_FUNCTIONAL. Similarly, the ITMETH parameter has been removed from the Fortran interface function FCVMALLOC. Instead of specifying the nonlinear iteration type when creating the CVODE memory structure, CVODE uses the SUNNONLINSOL_NEWTON module implementation of a Newton iteration by default. To use the fixed-point nonlinear solver with CVODE a user must do the following:

- 1. include the header sunnonlinsol/sunnonlinsol_fixedpoint.h to access the SUNNONLINSOL_FIXEDPOINT module,
- 2. create a nonlinear solver object by calling the fixed-point constructor

```
NLS = SUNNonlinSol_FixedPoint(y, m);
```

where NLS is the nonlinear solver object of type SUNNonlinearSolver, y is an NVector the size of the ODE system, and m is the number of acceleration vectors (see §9.3 for more detail), and

3. after initializing CVODE with CVodeInit, call

```
retval = CVodeSetNonlinearSolver(cvode_mem, NLS);
```

to attach the nonlinear solver object to the CVODE memory structure.

User-supplied nonlinear solver modules adhering to the Sunnonlinsol API for solving F(y) = 0 or G(y) = y can be used with CVODE by following the same include, create, and attach process just described for the Sunnonlinsol_fixedpoint module.

As a result of this new nonlinear solver object creation and attachment approach, the function CVodeSetIterType has been removed. CVODE functions for setting the nonlinear solver options (e.g., CVodeSetMaxNonlinIters) or getting nonlinear solver statistics (e.g., CVodeGetNumNonlinSolvIters) remain unchanged and internally call generic SUNNONLINSOL functions.

Changes in v4.0.0-dev

Three fused vector operations and seven vector array operations have been added to the NVECTOR API. These *optional* operations are intended to increase data reuse in vector operations, reduce parallel communication on distributed memory systems, and lower the number of kernel launches on systems with accelerators. The new operations are N_VLinearCombination, N_VScaleAddMulti, N_VDotProdMulti, N_VLinearCombinationVectorArray, N_VScaleVectorArray, N_VConstVectorArray,

N_VWrmsNormVectorArray, N_VWrmsNormMaskVectorArray, N_VScaleAddMultiVectorArray, and N_VLinearCombinationVectorArray. If any of these operations are defined as NULL in an NVECTOR implementation the NVECTOR interface will automatically call standard NVECTOR operations as necessary. Details on the new operations can be found in Chapter 6.

Several changes were made to the build system. If MPI is enabled and MPI compiler wrappers are not set, the build system will check if CMAKE_<language>_COMPILER can compile MPI programs before trying to locate and use an MPI installation. The native CMake FindMPI module is now used to locate an MPI installation. The options for setting MPI compiler wrappers and the executable for running MPI programs have been updated to align with those in native CMake FindMPI module. This included changing MPI_MPICC to MPI_C_COMPILER, MPI_MPICXX to MPI_CXX_COMPILER, combining MPI_MPIF77 and MPI_MPIF90 to MPI_Fortran_COMPILER, and changing MPI_RUN_COMMAND to MPIEXEC_EXECUTABLE. When a Fortran name-mangling scheme is needed (e.g., LAPACK_ENABLE is ON) the build system will infer the scheme from the Fortran compiler. If a Fortran compiler is not available or the inferred or default scheme needs to be overridden, the advanced options SUNDIALS_F77_FUNC_CASE and SUNDIALS_F77_FUNC_UNDERSCORES can be used to manually set the name-mangling scheme and bypass trying to infer the scheme. Additionally, parts of the main CMakeLists.txt file were moved to new files in the src and example directories to make the CMake configuration file structure more modular.

Changes in v3.1.2

The changes in this minor release include the following:

- Updated the minimum required version of CMake to 2.8.12 and enabled using rpath by default to locate shared libraries on OSX.
- Fixed Windows specific problem where sunindextype was not correctly defined when using 64-bit integers for the SUNDIALS index type. On Windows sunindextype is now defined as the MSVC basic type __int64.
- Added sparse SUNMatrix "Reallocate" routine to allow specification of the nonzero storage.
- Updated the KLU SUNLinearSolver module to set constants for the two reinitialization types, and fixed a bug in the full reinitialization approach where the sparse SUNMatrix pointer would go out of scope on some architectures.
- Updated the "ScaleAdd" and "ScaleAddI" implementations in the sparse SUNMatrix module to more optimally handle the case where the target matrix contained sufficient storage for the sum, but had the wrong sparsity pattern. The sum now occurs in-place, by performing the sum backwards in the existing storage. However, it is still more efficient if the user-supplied Jacobian routine allocates storage for the sum $I + \gamma J$ manually (with zero entries if needed).

4 Introduction

• Added the following examples from the usage notes page of the SUNDIALS website, and updated them to work with SUNDIALS 3.x:

- cvDisc_dns.c, which demonstrates using CVODE with discontinuous solutions or RHS.
- cvRoberts_dns_negsol.c, which illustrates the use of the RHS function return value to control unphysical negative concentrations.
- Changed the LICENSE install path to instdir/include/sundials.

Changes in v3.1.1

The changes in this minor release include the following:

- Fixed a minor bug in the cvSLdet routine, where a return was missing in the error check for three inconsistent roots.
- Fixed a potential memory leak in the SPGMR and SPFGMR linear solvers: if "Initialize" was called multiple times then the solver memory was reallocated (without being freed).
- Updated KLU SUNLINEARSOLVER module to use a typedef for the precision-specific solve function to be used (to avoid compiler warnings).
- Added missing typecasts for some (void*) pointers (again, to avoid compiler warnings).
- Bugfix in sunmatrix_sparse.c where we had used int instead of sunindextype in one location.
- Added missing #include <stdio.h> in NVECTOR and SUNMATRIX header files.
- Fixed an indexing bug in the CUDA NVECTOR implementation of N_VWrmsNormMask and revised the RAJA NVECTOR implementation of N_VWrmsNormMask to work with mask arrays using values other than zero or one. Replaced double with realtype in the RAJA vector test functions.
- Fixed compilation issue with GCC 7.3.0 and Fortran programs that do not require a SUNMATRIX or SUNLINSOL module (e.g., iterative linear solvers or fixed-point iteration).

In addition to the changes above, minor corrections were also made to the example programs, build system, and user documentation.

Changes in v3.1.0

Added NVECTOR print functions that write vector data to a specified file (e.g., N_VPrintFile_Serial). Added make test and make test_install options to the build system for testing SUNDIALS after building with make and installing with make install respectively.

Changes in v3.0.0

All interfaces to matrix structures and linear solvers have been reworked, and all example programs have been updated. The goal of the redesign of these interfaces was to provide more encapsulation and ease in interfacing custom linear solvers and interoperability with linear solver libraries. Specific changes include:

- Added generic SUNMATRIX module with three provided implementations: dense, banded and sparse. These replicate previous SUNDIALS Dls and Sls matrix structures in a single objectoriented API.
- Added example problems demonstrating use of generic SUNMATRIX modules.

- Added generic SUNLINEARSOLVER module with eleven provided implementations: dense, banded, LAPACK dense, LAPACK band, KLU, SuperLU_MT, SPGMR, SPBCGS, SPTFQMR, SPFGMR, PCG. These replicate previous SUNDIALS generic linear solvers in a single objectoriented API.
- Added example problems demonstrating use of generic SUNLINEARSOLVER modules.
- Expanded package-provided direct linear solver (Dls) interfaces and scaled, preconditioned, iterative linear solver (Spils) interfaces to utilize generic SUNMATRIX and SUNLINEARSOLVER objects.
- Removed package-specific, linear solver-specific, solver modules (e.g. CVDENSE, KINBAND, IDAKLU, ARKSPGMR) since their functionality is entirely replicated by the generic Dls/Spils interfaces and SUNLINEARSOLVER/SUNMATRIX modules. The exception is CVDIAG, a diagonal approximate Jacobian solver available to CVODE and CVODES.
- Converted all SUNDIALS example problems to utilize new generic SUNMATRIX and SUNLIN-EARSOLVER objects, along with updated Dls and Spils linear solver interfaces.
- Added Spils interface routines to ARKode, CVODE, CVODES, IDA and IDAS to allow specification of a user-provided "JTSetup" routine. This change supports users who wish to set up data structures for the user-provided Jacobian-times-vector ("JTimes") routine, and where the cost of one JTSetup setup per Newton iteration can be amortized between multiple JTimes calls.

Two additional NVECTOR implementations were added – one for CUDA and one for RAJA vectors. These vectors are supplied to provide very basic support for running on GPU architectures. Users are advised that these vectors both move all data to the GPU device upon construction, and speedup will only be realized if the user also conducts the right-hand-side function evaluation on the device. In addition, these vectors assume the problem fits on one GPU. Further information about RAJA, users are referred to the web site, https://software.llnl.gov/RAJA/. These additions are accompanied by additions to various interface functions and to user documentation.

All indices for data structures were updated to a new sunindextype that can be configured to be a 32- or 64-bit integer data index type. sunindextype is defined to be int32_t or int64_t when portable types are supported, otherwise it is defined as int or long int. The Fortran interfaces continue to use long int for indices, except for their sparse matrix interface that now uses the new sunindextype. This new flexible capability for index types includes interfaces to PETSc, hypre, SuperLU_MT, and KLU with either 32-bit or 64-bit capabilities depending how the user configures SUNDIALS.

To avoid potential namespace conflicts, the macros defining booleantype values TRUE and FALSE have been changed to SUNTRUE and SUNFALSE respectively.

Temporary vectors were removed from preconditioner setup and solve routines for all packages. It is assumed that all necessary data for user-provided preconditioner operations will be allocated and stored in user-provided data structures.

The file include/sundials_fconfig.h was added. This file contains SUNDIALS type information for use in Fortran programs.

Added functions SUNDIALSGetVersion and SUNDIALSGetVersionNumber to get SUNDIALS release version information at runtime.

The build system was expanded to support many of the xSDK-compliant keys. The xSDK is a movement in scientific software to provide a foundation for the rapid and efficient production of high-quality, sustainable extreme-scale scientific applications. More information can be found at, https://xsdk.info.

In addition, numerous changes were made to the build system. These include the addition of separate BLAS_ENABLE and BLAS_LIBRARIES CMake variables, additional error checking during CMake configuration, minor bug fixes, and renaming CMake options to enable/disable examples for greater clarity and an added option to enable/disable Fortran 77 examples. These changes included changing

6 Introduction

EXAMPLES_ENABLE to EXAMPLES_ENABLE_C, changing CXX_ENABLE to EXAMPLES_ENABLE_CXX, changing F90_ENABLE to EXAMPLES_ENABLE_F90, and adding an EXAMPLES_ENABLE_F77 option.

A bug fix was made in CVodeFree to call lfree unconditionally (if non-NULL).

Corrections and additions were made to the examples, to installation-related files, and to the user documentation.

Changes in v2.9.0

Two additional NVECTOR implementations were added – one for Hypre (parallel) ParVector vectors, and one for PETSc vectors. These additions are accompanied by additions to various interface functions and to user documentation.

Each NVECTOR module now includes a function, N_VGetVectorID, that returns the NVECTOR module name.

For each linear solver, the various solver performance counters are now initialized to 0 in both the solver specification function and in solver linit function. This ensures that these solver counters are initialized upon linear solver instantiation as well as at the beginning of the problem solution.

In FCVODE, corrections were made to three Fortran interface functions. Missing Fortran interface routines were added so that users can supply the sparse Jacobian routine when using sparse direct solvers.

A memory leak was fixed in the banded preconditioner interface. In addition, updates were done to return integers from linear solver and preconditioner 'free' functions.

The Krylov linear solver Bi-CGstab was enhanced by removing a redundant dot product. Various additions and corrections were made to the interfaces to the sparse solvers KLU and SuperLU_MT, including support for CSR format when using KLU.

New examples were added for use of the OpenMP vector and for use of sparse direct solvers from Fortran.

Minor corrections and additions were made to the CVODE solver, to the Fortran interfaces, to the examples, to installation-related files, and to the user documentation.

Changes in v2.8.0

Two major additions were made to the linear system solvers that are available for use with the CVODE solver. First, in the serial case, an interface to the sparse direct solver KLU was added. Second, an interface to SuperLU_MT, the multi-threaded version of SuperLU, was added as a thread-parallel sparse direct solver option, to be used with the serial version of the NVECTOR module. As part of these additions, a sparse matrix (CSC format) structure was added to CVODE.

Otherwise, only relatively minor modifications were made to the CVODE solver:

In cvRootfind, a minor bug was corrected, where the input array rootdir was ignored, and a line was added to break out of root-search loop if the initial interval size is below the tolerance ttol.

In CVLapackBand, the line smu = MIN(N-1,mu+ml) was changed to smu = mu + ml to correct an illegal input error for DGBTRF/DGBTRS.

In order to eliminate or minimize the differences between the sources for private functions in CVODE and CVODES, the names of 48 private functions were changed from CV** to cv**, and a few other names were also changed.

Two minor bugs were fixed regarding the testing of input on the first call to CVode – one involving tstop and one involving the initialization of *tret.

In order to avoid possible name conflicts, the mathematical macro and function names MIN, MAX, SQR, RAbs, RSqrt, RExp, RPowerI, and RPowerR were changed to SUNMIN, SUNMAX, SUNSQR, SUNRabs, SUNRsqrt, SUNRexp, SRpowerI, and SUNRpowerR, respectively. These names occur in both the solver and in various example programs.

The example program cvAdvDiff_diag_p was added to illustrate the use of CVDiag in parallel.

In the FCVODE optional input routines FCVSETIIN and FCVSETRIN, the optional fourth argument key_length was removed, with hardcoded key string lengths passed to all strncmp tests.

In all FCVODE examples, integer declarations were revised so that those which must match a C type long int are declared INTEGER*8, and a comment was added about the type match. All other integer declarations are just INTEGER. Corresponding minor corrections were made to the user guide.

Two new NVECTOR modules have been added for thread-parallel computing environments — one for OpenMP, denoted NVECTOR_OPENMP, and one for Pthreads, denoted NVECTOR_PTHREADS.

With this version of SUNDIALS, support and documentation of the Autotools mode of installation is being dropped, in favor of the CMake mode, which is considered more widely portable.

Changes in v2.7.0

One significant design change was made with this release: The problem size and its relatives, bandwidth parameters, related internal indices, pivot arrays, and the optional output lsflag have all been changed from type int to type long int, except for the problem size and bandwidths in user calls to routines specifying BLAS/LAPACK routines for the dense/band linear solvers. The function NewIntArray is replaced by a pair NewIntArray/NewLintArray, for int and long int arrays, respectively.

A large number of minor errors have been fixed. Among these are the following: In CVSetTqBDF, the logic was changed to avoid a divide by zero. After the solver memory is created, it is set to zero before being filled. In each linear solver interface function, the linear solver memory is freed on an error return, and the **Free function now includes a line setting to NULL the main memory pointer to the linear solver memory. In the rootfinding functions CVRcheck1/CVRcheck2, when an exact zero is found, the array glo of g values at the left endpoint is adjusted, instead of shifting the t location tlo slightly. In the installation files, we modified the treatment of the macro SUNDIALS_USE_GENERIC_MATH, so that the parameter GENERIC_MATH_LIB is either defined (with no value) or not defined.

Changes in v2.6.0

Two new features were added in this release: (a) a new linear solver module, based on BLAS and LAPACK for both dense and banded matrices, and (b) an option to specify which direction of zero-crossing is to be monitored while performing rootfinding.

The user interface has been further refined. Some of the API changes involve: (a) a reorganization of all linear solver modules into two families (besides the existing family of scaled preconditioned iterative linear solvers, the direct solvers, including the new LAPACK-based ones, were also organized into a *direct* family); (b) maintaining a single pointer to user data, optionally specified through a Set-type function; and (c) a general streamlining of the preconditioner modules distributed with the solver.

Changes in v2.5.0

The main changes in this release involve a rearrangement of the entire SUNDIALS source tree (see §3.1). At the user interface level, the main impact is in the mechanism of including SUNDIALS header files which must now include the relative path (e.g. #include <cvode/cvode.h>). Additional changes were made to the build system: all exported header files are now installed in separate subdirectories of the instaltion *include* directory.

The functions in the generic dense linear solver (sundials_dense and sundials_smalldense) were modified to work for rectangular $m \times n$ matrices ($m \le n$), while the factorization and solution functions were renamed to DenseGETRF/denGETRF and DenseGETRS/denGETRS, respectively. The factorization and solution functions in the generic band linear solver were renamed BandGBTRF and BandGBTRS, respectively.

Changes in v2.4.0

CVSPBCG and CVSPTFQMR modules have been added to interface with the Scaled Preconditioned Bi-CGstab (SPBCGS) and Scaled Preconditioned Transpose-Free Quasi-Minimal Residual (SPTFQMR)

8 Introduction

linear solver modules, respectively (for details see Chapter 4). Corresponding additions were made to the FORTRAN interface module FCVODE. At the same time, function type names for Scaled Preconditioned Iterative Linear Solvers were added for the user-supplied Jacobian-times-vector and preconditioner setup and solve functions.

The deallocation functions now take as arguments the address of the respective memory block pointer.

To reduce the possibility of conflicts, the names of all header files have been changed by adding unique prefixes (cvode_ and sundials_). When using the default installation procedure, the header files are exported under various subdirectories of the target include directory. For more details see Appendix A.

Changes in v2.3.0

The user interface has been further refined. Several functions used for setting optional inputs were combined into a single one. An optional user-supplied routine for setting the error weight vector was added. Additionally, to resolve potential variable scope issues, all SUNDIALS solvers release user data right after its use. The build systems has been further improved to make it more robust.

Changes in v2.2.1

The changes in this minor SUNDIALS release affect only the build system.

Changes in v2.2.0

The major changes from the previous version involve a redesign of the user interface across the entire SUNDIALS suite. We have eliminated the mechanism of providing optional inputs and extracting optional statistics from the solver through the iopt and ropt arrays. Instead, CVODE now provides a set of routines (with prefix CVodeSet) to change the default values for various quantities controlling the solver and a set of extraction routines (with prefix CVodeGet) to extract statistics after return from the main solver routine. Similarly, each linear solver module provides its own set of Set- and Get-type routines. For more details see §4.5.7 and §4.5.9.

Additionally, the interfaces to several user-supplied routines (such as those providing Jacobians and preconditioner information) were simplified by reducing the number of arguments. The same information that was previously accessible through such arguments can now be obtained through Get-type functions.

The rootfinding feature was added, whereby the roots of a set of given functions may be computed during the integration of the ODE system.

Installation of CVODE (and all of SUNDIALS) has been completely redesigned and is now based on configure scripts.

1.3 Reading this User Guide

This user guide is a combination of general usage instructions. Specific example programs are provided as a separate document. We expect that some readers will want to concentrate on the general instructions, while others will refer mostly to the examples, and the organization is intended to accommodate both styles.

There are different possible levels of usage of CVODE. The most casual user, with a small IVP problem only, can get by with reading §2.1, then Chapter 4 through §4.5.6 only, and looking at examples in [27].

In a different direction, a more expert user with an IVP problem may want to (a) use a package preconditioner (§4.7), (b) supply his/her own Jacobian or preconditioner routines (§4.6), (c) do multiple runs of problems of the same size (§4.5.10), (d) supply a new NVECTOR module (Chapter 6), (e) supply new SUNLINSOL and/or SUNMATRIX modules (Chapters 7 and 8), or even (f) supply new SUNNONLINSOL modules (Chapter 9).

The structure of this document is as follows:

- In Chapter 2, we give short descriptions of the numerical methods implemented by CVODE for the solution of initial value problems for systems of ODEs, and continue with short descriptions of preconditioning (§2.2), stability limit detection (§2.3), and rootfinding (§2.4).
- The following chapter describes the structure of the SUNDIALS suite of solvers (§3.1) and the software organization of the CVODE solver (§3.2).
- Chapter 4 is the main usage document for CVODE for C applications. It includes a complete description of the user interface for the integration of ODE initial value problems.
- In Chapter 5, we describe FCVODE, an interface module for the use of CVODE with FORTRAN applications.
- Chapter 6 gives a brief overview of the generic NVECTOR module shared among the various components of SUNDIALS, and details on the NVECTOR implementations provided with SUNDIALS.
- Chapter 7 gives a brief overview of the generic SUNMATRIX module shared among the various components of SUNDIALS, and details on the SUNMATRIX implementations provided with SUNDIALS: a dense implementation (§7.1), a banded implementation (§7.2) and a sparse implementation (§7.3).
- Chapter 8 gives a brief overview of the generic Sunlinsol module shared among the various components of Sundials. This chapter contains details on the Sunlinsol implementations provided with Sundials. The chapter also contains details on the Sunlinsol implementations provided with Sundials that interface with external linear solver libraries.
- Chapter 9 describes the SUNNONLINSOL API and nonlinear solver implementations shared among the various components of SUNDIALS.
- Finally, in the appendices, we provide detailed instructions for the installation of CVODE, within the structure of SUNDIALS (Appendix A), as well as a list of all the constants used for input to and output from CVODE functions (Appendix B).

Finally, the reader should be aware of the following notational conventions in this user guide: program listings and identifiers (such as CVodeInit) within textual explanations appear in typewriter type style; fields in C structures (such as content) appear in italics; and packages or modules, such as CVDLS, are written in all capitals. Usage and installation instructions that constitute important warnings are marked with a triangular symbol in the margin.

Acknowledgments. We wish to acknowledge the contributions to previous versions of the CVODE and PVODE codes and their user guides by Scott D. Cohen [12] and George D. Byrne [10].

1.4 SUNDIALS Release License

The SUNDIALS packages are released open source, under a BSD license. The only requirements of the BSD license are preservation of copyright and a standard disclaimer of liability. Our Copyright notice is below along with the license.

PLEASE NOTE If you are using SUNDIALS with any third party libraries linked in (e.g., LaPACK, KLU, SuperLU_MT, PETSC, or hypre), be sure to review the respective license of the package as that license may have more restrictive terms than the SUNDIALS license. For example, if someone builds SUNDIALS with a statically linked KLU, the build is subject to terms of the LGPL license (which is what KLU is released with) and *not* the SUNDIALS BSD license anymore.

1.4.1 Copyright Notices

Chapter 2

Mathematical Considerations

CVODE solves ODE initial value problems (IVPs) in real N-space, which we write in the abstract form

$$\dot{y} = f(t, y), \quad y(t_0) = y_0,$$
 (2.1)

where $y \in \mathbf{R}^N$. Here we use \dot{y} to denote dy/dt. While we use t to denote the independent variable, and usually this is time, it certainly need not be. CVODE solves both stiff and nonstiff systems. Roughly speaking, stiffness is characterized by the presence of at least one rapidly damped mode, whose time constant is small compared to the time scale of the solution itself.

2.1 IVP solution

The methods used in CVODE are variable-order, variable-step multistep methods, based on formulas of the form

$$\sum_{i=0}^{K_1} \alpha_{n,i} y^{n-i} + h_n \sum_{i=0}^{K_2} \beta_{n,i} \dot{y}^{n-i} = 0.$$
 (2.2)

Here the y^n are computed approximations to $y(t_n)$, and $h_n = t_n - t_{n-1}$ is the step size. The user of CVODE must choose appropriately one of two multistep methods. For nonstiff problems, CVODE includes the Adams-Moulton formulas, characterized by $K_1 = 1$ and $K_2 = q$ above, where the order q varies between 1 and 12. For stiff problems, CVODE includes the Backward Differentiation Formulas (BDF) in so-called fixed-leading coefficient (FLC) form, given by $K_1 = q$ and $K_2 = 0$, with order q varying between 1 and 5. The coefficients are uniquely determined by the method type, its order, the recent history of the step sizes, and the normalization $\alpha_{n,0} = -1$. See [9] and [29].

For either choice of formula, a nonlinear system must be solved (approximately) at each integration step. This nonlinear system can formulated as either a rootfinding problem

$$F(y^n) \equiv y^n - h_n \beta_{n,0} f(t_n, y^n) - a_n = 0, \qquad (2.3)$$

or as a fixed-point problem

$$G(y^n) \equiv h_n \beta_{n,0} f(t_n, y^n) + a_n = y^n.$$
 (2.4)

where $a_n \equiv \sum_{i>0} (\alpha_{n,i} y^{n-i} + h_n \beta_{n,i} \dot{y}^{n-i})$. CVODE provides several nonlinear solver choices as well as the option of using a user-defined nonlinear solver (see Chapter 9). By default CVODE solves (2.3) with a *Newton iteration* which requires the solution of linear systems

$$M[y^{n(m+1)} - y^{n(m)}] = -F(y^{n(m)}), (2.5)$$

in which

$$M \approx I - \gamma J$$
, $J = \partial f / \partial y$, and $\gamma = h_n \beta_{n,0}$. (2.6)

The exact variation of the Newton iteration depends on the choice of linear solver and is discussed below and in §9.2. For nonstiff systems, a fixed-point iteration (previously referred to as a functional

iteration in this guide) solving (2.4) is also available. This involves evaluations of f only and can (optionally) use Anderson's method [3, 38, 18, 32] to accelerate convergence (see §9.3 for more details). For any nonlinear solver, the initial guess for the iteration is a predicted value $y^{n(0)}$ computed explicitly from the available history data.

For nonlinear solvers that require the solution of the linear system (2.5) (e.g., the default Newton iteration), CVODE provides several linear solver choices, including the option of a user-supplied linear solver module (see Chapter 8). The linear solver modules distributed with SUNDIALS are organized in two families, a *direct* family comprising direct linear solvers for dense, banded, or sparse matrices, and a *spils* family comprising scaled preconditioned iterative (Krylov) linear solvers. The methods offered through these modules are as follows:

- dense direct solvers, using either an internal implementation or a BLAS/LAPACK implementation (serial or threaded vector modules only),
- band direct solvers, using either an internal implementation or a BLAS/LAPACK implementation (serial or threaded vector modules only),
- sparse direct solver interfaces, using either the KLU sparse solver library [14, 1], or the threadenabled SuperLU_MT sparse solver library [31, 16, 2] (serial or threaded vector modules only) [Note that users will need to download and install the KLU or SUPERLUMT packages independent of CVODE],
- SPGMR, a scaled preconditioned GMRES (Generalized Minimal Residual method) solver,
- SPFGMR, a scaled preconditioned FGMRES (Flexible Generalized Minimal Residual method) solver,
- SPBCGS, a scaled preconditioned Bi-CGStab (Bi-Conjugate Gradient Stable method) solver,
- SPTFQMR, a scaled preconditioned TFQMR (Transpose-Free Quasi-Minimal Residual method) solver, or
- PCG, a scaled preconditioned CG (Conjugate Gradient method) solver.

For large stiff systems, where direct methods are not feasible, the combination of a BDF integrator and a preconditioned Krylov method yields a powerful tool because it combines established methods for stiff integration, nonlinear iteration, and Krylov (linear) iteration with a problem-specific treatment of the dominant source of stiffness, in the form of the user-supplied preconditioner matrix [6].

In addition, CVODE also provides a linear solver module which only uses a diagonal approximation of the Jacobian matrix.

Note that the dense, band, and sparse direct linear solvers can only be used with the serial and threaded vector representations. The diagonal solver can be used with any vector representation.

In the process of controlling errors at various levels, CVODE uses a weighted root-mean-square norm, denoted $\|\cdot\|_{WRMS}$, for all error-like quantities. The multiplicative weights used are based on the current solution and on the relative and absolute tolerances input by the user, namely

$$W_i = 1/[\text{RTOL} \cdot |y_i| + \text{ATOL}_i]. \tag{2.7}$$

Because $1/W_i$ represents a tolerance in the component y_i , a vector whose norm is 1 is regarded as "small." For brevity, we will usually drop the subscript WRMS on norms in what follows.

In the cases of a direct solver (dense, band, sparse, or diagonal), the default Newton iteration is a Modified Newton iteration, in that the iteration matrix M is fixed throughout the nonlinear iterations. However, for any of the Krylov methods, it is an Inexact Newton iteration, in which M is applied in a matrix-free manner, with matrix-vector products Jv obtained by either difference quotients or a user-supplied routine. With the default Newton iteration, the matrix M (direct cases) or preconditioner matrix P (Krylov cases) is updated as infrequently as possible to balance the high costs of matrix operations against other costs. Specifically, this matrix update occurs when:

2.1 IVP solution 15

- starting the problem,
- more than 20 steps have been taken since the last update,
- the value $\bar{\gamma}$ of γ at the last update satisfies $|\gamma/\bar{\gamma}-1|>0.3$,
- a non-fatal convergence failure just occurred, or
- an error test failure just occurred.

When forced by a convergence failure, an update of M or P may or may not involve a reevaluation of J (in M) or of Jacobian data (in P), depending on whether Jacobian error was the likely cause of the failure. More generally, the decision is made to reevaluate J (or instruct the user to reevaluate Jacobian data in P) when:

- starting the problem,
- more than 50 steps have been taken since the last evaluation,
- a convergence failure occurred with an outdated matrix, and the value $\bar{\gamma}$ of γ at the last update satisfies $|\gamma/\bar{\gamma}-1|<0.2$, or
- a convergence failure occurred that forced a step size reduction.

The default stopping test for nonlinear solver iterations is related to the subsequent local error test, with the goal of keeping the nonlinear iteration errors from interfering with local error control. As described below, the final computed value $y^{n(m)}$ will have to satisfy a local error test $||y^{n(m)} - y^{n(0)}|| \le \epsilon$. Letting y^n denote the exact solution of (2.3), we want to ensure that the iteration error $y^n - y^{n(m)}$ is small relative to ϵ , specifically that it is less than 0.1ϵ . (The safety factor 0.1 can be changed by the user.) For this, we also estimate the linear convergence rate constant R as follows. We initialize R to 1, and reset R = 1 when M or P is updated. After computing a correction $\delta_m = y^{n(m)} - y^{n(m-1)}$, we update R if m > 1 as

$$R \leftarrow \max\{0.3R, \|\delta_m\|/\|\delta_{m-1}\|\}.$$

Now we use the estimate

$$||y^n - y^{n(m)}|| \approx ||y^{n(m+1)} - y^{n(m)}|| \approx R||y^{n(m)} - y^{n(m-1)}|| = R||\delta_m||.$$

Therefore the convergence (stopping) test is

$$R\|\delta_m\| < 0.1\epsilon$$
.

We allow at most 3 iterations (but this limit can be changed by the user). We also declare the iteration diverged if any $\|\delta_m\|/\|\delta_{m-1}\| > 2$ with m > 1. If convergence fails with J or P current, we are forced to reduce the step size, and we replace h_n by $h_n/4$. The integration is halted after a preset number of convergence failures; the default value of this limit is 10, but this can be changed by the user.

When a Krylov method is used to solve the linear system, its errors must also be controlled, and this also involves the local error test constant. The linear iteration error in the solution vector δ_m is approximated by the preconditioned residual vector. Thus to ensure (or attempt to ensure) that the linear iteration errors do not interfere with the nonlinear error and local integration error controls, we require that the norm of the preconditioned residual be less than $0.05 \cdot (0.1\epsilon)$.

With the direct dense and band methods, the Jacobian may be supplied by a user routine, or approximated by difference quotients, at the user's option. In the latter case, we use the usual approximation

$$J_{ij} = [f_i(t, y + \sigma_j e_j) - f_i(t, y)]/\sigma_j.$$

The increments σ_i are given by

$$\sigma_j = \max \left\{ \sqrt{U} |y_j|, \sigma_0/W_j \right\},$$

where U is the unit roundoff, σ_0 is a dimensionless value, and W_j is the error weight defined in (2.7). In the dense case, this scheme requires N evaluations of f, one for each column of J. In the band case, the columns of J are computed in groups, by the Curtis-Powell-Reid algorithm, with the number of f evaluations equal to the bandwidth.

We note that with the sparse direct solvers, the Jacobian *must* be supplied by a user routine.

In the case of a Krylov method, preconditioning may be used on the left, on the right, or both, with user-supplied routines for the preconditioning setup and solve operations, and optionally also for the required matrix-vector products Jv. If a routine for Jv is not supplied, these products are computed as

$$Jv = [f(t, y + \sigma v) - f(t, y)]/\sigma.$$
(2.8)

The increment σ is 1/||v||, so that σv has norm 1.

A critical part of CVODE — making it an ODE "solver" rather than just an ODE method, is its control of local error. At every step, the local error is estimated and required to satisfy tolerance conditions, and the step is redone with reduced step size whenever that error test fails. As with any linear multistep method, the local truncation error LTE, at order q and step size h, satisfies an asymptotic relation

$$LTE = Ch^{q+1}y^{(q+1)} + O(h^{q+2})$$

for some constant C, under mild assumptions on the step sizes. A similar relation holds for the error in the predictor $y^{n(0)}$. These are combined to get a relation

LTE =
$$C'[y^n - y^{n(0)}] + O(h^{q+2})$$
.

The local error test is simply $\|\text{LTE}\| \le 1$. Using the above, it is performed on the predictor-corrector difference $\Delta_n \equiv y^{n(m)} - y^{n(0)}$ (with $y^{n(m)}$ the final iterate computed), and takes the form

$$\|\Delta_n\| \le \epsilon \equiv 1/|C'|$$
.

If this test passes, the step is considered successful. If it fails, the step is rejected and a new step size h' is computed based on the asymptotic behavior of the local error, namely by the equation

$$(h'/h)^{q+1} \|\Delta_n\| = \epsilon/6.$$

Here 1/6 is a safety factor. A new attempt at the step is made, and the error test repeated. If it fails three times, the order q is reset to 1 (if q > 1), or the step is restarted from scratch (if q = 1). The ratio h'/h is limited above to 0.2 after two error test failures, and limited below to 0.1 after three. After seven failures, CVODE returns to the user with a give-up message.

In addition to adjusting the step size to meet the local error test, CVODE periodically adjusts the order, with the goal of maximizing the step size. The integration starts out at order 1 and varies the order dynamically after that. The basic idea is to pick the order q for which a polynomial of order q best fits the discrete data involved in the multistep method. However, if either a convergence failure or an error test failure occurred on the step just completed, no change in step size or order is done. At the current order q, selecting a new step size is done exactly as when the error test fails, giving a tentative step size ratio

$$h'/h = (\epsilon/6||\Delta_n||)^{1/(q+1)} \equiv \eta_q.$$

We consider changing order only after taking q+1 steps at order q, and then we consider only orders q'=q-1 (if q>1) or q'=q+1 (if q<5). The local truncation error at order q' is estimated using the history data. Then a tentative step size ratio is computed on the basis that this error, LTE(q'), behaves asymptotically as $h^{q'+1}$. With safety factors of 1/6 and 1/10 respectively, these ratios are:

$$h'/h = [1/6||\text{LTE}(q-1)||]^{1/q} \equiv \eta_{q-1}$$

and

$$h'/h = [1/10||\text{LTE}(q+1)||]^{1/(q+2)} \equiv \eta_{q+1}$$
.

The new order and step size are then set according to

$$\eta = \max\{\eta_{q-1}, \eta_q, \eta_{q+1}\}, \quad h' = \eta h,$$

with q' set to the index achieving the above maximum. However, if we find that $\eta < 1.5$, we do not bother with the change. Also, h'/h is always limited to 10, except on the first step, when it is limited to 10^4 .

The various algorithmic features of CVODE described above, as inherited from VODE and VODPK, are documented in [5, 8, 24]. They are also summarized in [25].

Normally, CVODE takes steps until a user-defined output value $t = t_{\text{out}}$ is overtaken, and then it computes $y(t_{\text{out}})$ by interpolation. However, a "one step" mode option is available, where control returns to the calling program after each step. There are also options to force CVODE not to integrate past a given stopping point $t = t_{\text{stop}}$.

2.2 Preconditioning

When using a nonlinear solver that requires the solution of the linear system (2.5) (e.g., the default Newton iteration), CVODE makes repeated use of a linear solver to solve linear systems of the form Mx = -r, where x is a correction vector and r is a residual vector. If this linear system solve is done with one of the scaled preconditioned iterative linear solvers, these solvers are rarely successful if used without preconditioning; it is generally necessary to precondition the system in order to obtain acceptable efficiency. A system Ax = b can be preconditioned on the left, as $(P^{-1}A)x = P^{-1}b$; on the right, as $(AP^{-1})Px = b$; or on both sides, as $(P_L^{-1}AP_R^{-1})P_Rx = P_L^{-1}b$. The Krylov method is then applied to a system with the matrix $P^{-1}A$, or AP^{-1} , or $P_L^{-1}AP_R^{-1}$, instead of A. In order to improve the convergence of the Krylov iteration, the preconditioner matrix P, or the product P_LP_R in the last case, should in some sense approximate the system matrix P. Yet at the same time, in order to be cost-effective, the matrix P, or matrices P_L and P_R , should be reasonably efficient to evaluate and solve. Finding a good point in this tradeoff between rapid convergence and low cost can be very difficult. Good choices are often problem-dependent (for example, see [6] for an extensive study of preconditioners for reaction-transport systems).

Most of the iterative linear solvers supplied with SUNDIALS allow for preconditioning either side, or on both sides, although we know of no situation where preconditioning on both sides is clearly superior to preconditioning on one side only (with the product P_LP_R). Moreover, for a given preconditioner matrix, the merits of left vs. right preconditioning are unclear in general, and the user should experiment with both choices. Performance will differ because the inverse of the left preconditioner is included in the linear system residual whose norm is being tested in the Krylov algorithm. As a rule, however, if the preconditioner is the product of two matrices, we recommend that preconditioning be done either on the left only or the right only, rather than using one factor on each side.

Typical preconditioners used with CVODE are based on approximations to the system Jacobian, $J = \partial f/\partial y$. Since the matrix involved is $M = I - \gamma J$, any approximation \bar{J} to J yields a matrix that is of potential use as a preconditioner, namely $P = I - \gamma \bar{J}$. Because the Krylov iteration occurs within a nonlinear solver iteration and further also within a time integration, and since each of these iterations has its own test for convergence, the preconditioner may use a very crude approximation, as long as it captures the dominant numerical feature(s) of the system. We have found that the combination of a preconditioner with the Newton-Krylov iteration, using even a fairly poor approximation to the Jacobian, can be surprisingly superior to using the same matrix without Krylov acceleration (i.e., a modified Newton iteration), as well as to using the Newton-Krylov method with no preconditioning.

2.3 BDF stability limit detection

CVODE includes an algorithm, STALD (STAbility Limit Detection), which provides protection against potentially unstable behavior of the BDF multistep integration methods in certain situations, as described below.

When the BDF option is selected, CVODES uses Backward Differentiation Formula methods of orders 1 to 5. At order 1 or 2, the BDF method is A-stable, meaning that for any complex constant λ in the open left half-plane, the method is unconditionally stable (for any step size) for the standard scalar model problem $\dot{y} = \lambda y$. For an ODE system, this means that, roughly speaking, as long as all modes in the system are stable, the method is also stable for any choice of step size, at least in the sense of a local linear stability analysis.

At orders 3 to 5, the BDF methods are not A-stable, although they are stiffly stable. In each case, in order for the method to be stable at step size h on the scalar model problem, the product $h\lambda$ must lie within a region of absolute stability. That region excludes a portion of the left half-plane that is concentrated near the imaginary axis. The size of that region of instability grows as the order increases from 3 to 5. What this means is that, when running BDF at any of these orders, if an eigenvalue λ of the system lies close enough to the imaginary axis, the step sizes h for which the method is stable are limited (at least according to the linear stability theory) to a set that prevents $h\lambda$ from leaving the stability region. The meaning of close enough depends on the order. At order 3, the unstable region is much narrower than at order 5, so the potential for unstable behavior grows with order.

System eigenvalues that are likely to run into this instability are ones that correspond to weakly damped oscillations. A pure undamped oscillation corresponds to an eigenvalue on the imaginary axis. Problems with modes of that kind call for different considerations, since the oscillation generally must be followed by the solver, and this requires step sizes ($h \sim 1/\nu$, where ν is the frequency) that are stable for BDF anyway. But for a weakly damped oscillatory mode, the oscillation in the solution is eventually damped to the noise level, and at that time it is important that the solver not be restricted to step sizes on the order of $1/\nu$. It is in this situation that the new option may be of great value.

In terms of partial differential equations, the typical problems for which the stability limit detection option is appropriate are ODE systems resulting from semi-discretized PDEs (i.e., PDEs discretized in space) with advection and diffusion, but with advection dominating over diffusion. Diffusion alone produces pure decay modes, while advection tends to produce undamped oscillatory modes. A mix of the two with advection dominant will have weakly damped oscillatory modes.

The STALD algorithm attempts to detect, in a direct manner, the presence of a stability region boundary that is limiting the step sizes in the presence of a weakly damped oscillation [22]. The algorithm supplements (but differs greatly from) the existing algorithms in CVODES for choosing step size and order based on estimated local truncation errors. The STALD algorithm works directly with history data that is readily available in CVODE. If it concludes that the step size is in fact stability-limited, it dictates a reduction in the method order, regardless of the outcome of the error-based algorithm. The STALD algorithm has been tested in combination with the VODE solver on linear advection-dominated advection-diffusion problems [23], where it works well. The implementation in CVODE has been successfully tested on linear and nonlinear advection-diffusion problems, among others.

This stability limit detection option adds some computational overhead to the CVODES solution. (In timing tests, these overhead costs have ranged from 2% to 7% of the total, depending on the size and complexity of the problem, with lower relative costs for larger problems.) Therefore, it should be activated only when there is reasonable expectation of modes in the user's system for which it is appropriate. In particular, if a CVODE solution with this option turned off appears to take an inordinately large number of steps at orders 3-5 for no apparent reason in terms of the solution time scale, then there is a good chance that step sizes are being limited by stability, and that turning on the option will improve the efficiency of the solution.

2.4 Rootfinding

The CVODE solver has been augmented to include a rootfinding feature. This means that, while integrating the Initial Value Problem (2.1), CVODE can also find the roots of a set of user-defined functions $g_i(t, y)$ that depend both on t and on the solution vector y = y(t). The number of these root functions is arbitrary, and if more than one g_i is found to have a root in any given interval, the various root locations are found and reported in the order that they occur on the t axis, in the direction of

2.4 Rootfinding

integration.

Generally, this rootfinding feature finds only roots of odd multiplicity, corresponding to changes in sign of $g_i(t, y(t))$, denoted $g_i(t)$ for short. If a user root function has a root of even multiplicity (no sign change), it will probably be missed by CVODE. If such a root is desired, the user should reformulate the root function so that it changes sign at the desired root.

The basic scheme used is to check for sign changes of any $g_i(t)$ over each time step taken, and then (when a sign change is found) to hone in on the root(s) with a modified secant method [21]. In addition, each time g is computed, CVODE checks to see if $g_i(t) = 0$ exactly, and if so it reports this as a root. However, if an exact zero of any g_i is found at a point t, CVODE computes g at $t + \delta$ for a small increment δ , slightly further in the direction of integration, and if any $g_i(t + \delta) = 0$ also, CVODE stops and reports an error. This way, each time CVODE takes a time step, it is guaranteed that the values of all g_i are nonzero at some past value of t, beyond which a search for roots is to be done.

At any given time in the course of the time-stepping, after suitable checking and adjusting has been done, CVODE has an interval $(t_{lo}, t_{hi}]$ in which roots of the $g_i(t)$ are to be sought, such that t_{hi} is further ahead in the direction of integration, and all $g_i(t_{lo}) \neq 0$. The endpoint t_{hi} is either t_n , the end of the time step last taken, or the next requested output time t_{out} if this comes sooner. The endpoint t_{lo} is either t_{n-1} , the last output time t_{out} (if this occurred within the last step), or the last root location (if a root was just located within this step), possibly adjusted slightly toward t_n if an exact zero was found. The algorithm checks g_i at t_{hi} for zeros and for sign changes in (t_{lo}, t_{hi}) . If no sign changes were found, then either a root is reported (if some $g_i(t_{hi}) = 0$) or we proceed to the next time interval (starting at t_{hi}). If one or more sign changes were found, then a loop is entered to locate the root to within a rather tight tolerance, given by

$$\tau = 100 * U * (|t_n| + |h|)$$
 (U = unit roundoff).

Whenever sign changes are seen in two or more root functions, the one deemed most likely to have its root occur first is the one with the largest value of $|g_i(t_{hi})|/|g_i(t_{hi}) - g_i(t_{lo})|$, corresponding to the closest to t_{lo} of the secant method values. At each pass through the loop, a new value t_{mid} is set, strictly within the search interval, and the values of $g_i(t_{mid})$ are checked. Then either t_{lo} or t_{hi} is reset to t_{mid} according to which subinterval is found to include the sign change. If there is none in (t_{lo}, t_{mid}) but some $g_i(t_{mid}) = 0$, then that root is reported. The loop continues until $|t_{hi} - t_{lo}| < \tau$, and then the reported root location is t_{hi} .

In the loop to locate the root of $g_i(t)$, the formula for t_{mid} is

$$t_{mid} = t_{hi} - (t_{hi} - t_{lo})g_i(t_{hi})/[g_i(t_{hi}) - \alpha g_i(t_{lo})]$$

where α is a weight parameter. On the first two passes through the loop, α is set to 1, making t_{mid} the secant method value. Thereafter, α is reset according to the side of the subinterval (low vs. high, i.e., toward t_{lo} vs. toward t_{hi}) in which the sign change was found in the previous two passes. If the two sides were opposite, α is set to 1. If the two sides were the same, α is halved (if on the low side) or doubled (if on the high side). The value of t_{mid} is closer to t_{lo} when $\alpha < 1$ and closer to t_{hi} when $\alpha > 1$. If the above value of t_{mid} is within $\tau/2$ of t_{lo} or t_{hi} , it is adjusted inward, such that its fractional distance from the endpoint (relative to the interval size) is between .1 and .5 (.5 being the midpoint), and the actual distance from the endpoint is at least $\tau/2$.

Chapter 3

Code Organization

3.1 SUNDIALS organization

The family of solvers referred to as SUNDIALS consists of the solvers CVODE and ARKODE (for ODE systems), KINSOL (for nonlinear algebraic systems), and IDA (for differential-algebraic systems). In addition, SUNDIALS also includes variants of CVODE and IDA with sensitivity analysis capabilities (using either forward or adjoint methods), called CVODES and IDAS, respectively.

The various solvers of this family share many subordinate modules. For this reason, it is organized as a family, with a directory structure that exploits that sharing (see Figs. 3.1 and 3.2). The following is a list of the solver packages presently available, and the basic functionality of each:

- CVODE, a solver for stiff and nonstiff ODE systems dy/dt = f(t, y) based on Adams and BDF methods;
- CVODES, a solver for stiff and nonstiff ODE systems with sensitivity analysis capabilities;
- ARKODE, a solver for ODE systems $Mdy/dt = f_E(t, y) + f_I(t, y)$ based on additive Runge-Kutta methods;
- IDA, a solver for differential-algebraic systems $F(t, y, \dot{y}) = 0$ based on BDF methods;
- IDAS, a solver for differential-algebraic systems with sensitivity analysis capabilities;
- KINSOL, a solver for nonlinear algebraic systems F(u) = 0.

3.2 CVODE organization

The CVODE package is written in ANSI C. The following summarizes the basic structure of the package, although knowledge of this structure is not necessary for its use.

The overall organization of the CVODE package is shown in Figure 3.3. The central integration module, implemented in the files cvode.h, cvode_impl.h, and cvode.c, deals with the evaluation of integration coefficients, estimation of local error, selection of stepsize and order, and interpolation to user output points, among other issues.

CVODE utilizes generic linear and nonlinear solver modules defined by the SUNLINSOL API (see Chapter 8) and SUNNONLINSOL API (see Chapter 9) respectively. As such, CVODE has no knowledge of the method being used to solve the linear and nonlinear systems that arise. For any given user problem, there exists a single nonlinear solver interface and, if necessary, one of the linear system solver interfaces is specified, and invoked as needed during the integration.

At present, the package includes two linear solver interfaces. The *direct* linear solver interface, CVDLS, supports SUNLINSOL implementations with type SUNLINSOL DIRECT (see Chapter 8). These linear solvers utilize direct methods for the solution of linear systems stored using one of the SUNDIALS generic SUNMATRIX implementations (dense, banded or sparse; see Chapter 7). It is assumed that the

22 Code Organization

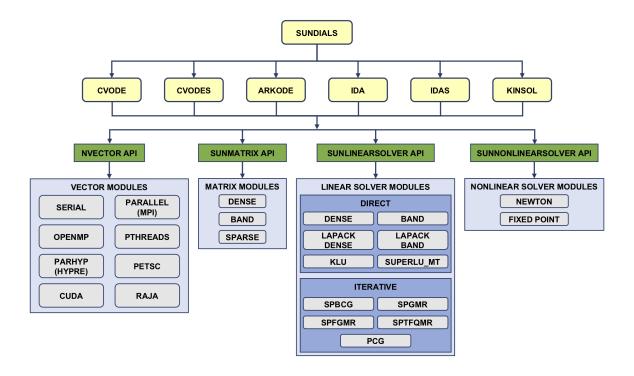

Figure 3.1: High-level diagram of the SUNDIALS suite

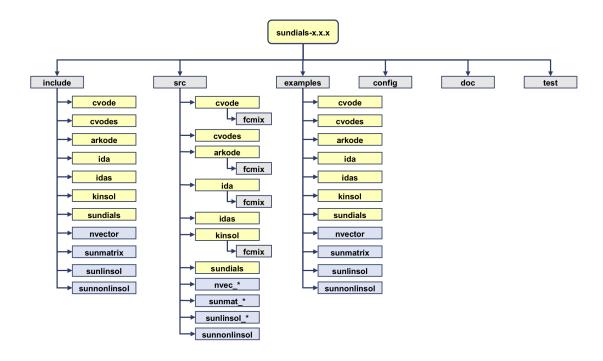

dominant cost for such solvers occurs in factorization of the linear system matrix M, so the Sunnonlinesollar solve. The spils linear solver interface, CVSPILS, supports Sunlinesollar implementations with type Sunlinesollar Sunlinesollar (see Chapter 8). These linear solvers utilize scaled preconditioned iterative methods. It is assumed that these methods are implemented in a "matrix-free" manner, wherein only the action of the matrix-vector product Mv is required. Since CVODE can operate on any valid Sunlinesoll implementation of Sunlinesoll director of Sunlinesoll interface, the set of linear solver modules available to CVODE will expand as new Sunlinesoll modules are developed.

Additionally, CVODE includes the *diagonal* linear solver interface, CVDIAG, that creates an internally generated diagonal approximation to the Jacobian.

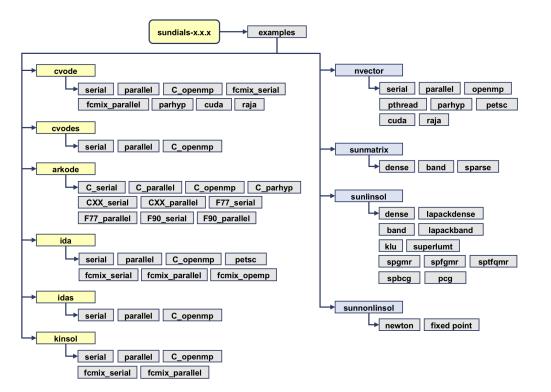

Within the CVDLS interface, the package includes algorithms for the approximation of dense or banded Jacobians through difference quotients, but the user also has the option of supplying the Jacobian (or an approximation to it) directly. This user-supplied routine is required when using sparse Jacobian matrices, since standard difference quotient approximations do not leverage the inherent sparsity of the problem.

Within the CVSPILS interface, the package includes an algorithm for the approximation by difference quotients of the product Mv. Again, the user has the option of providing routines for this operation, in two phases: setup (preprocessing of Jacobian data) and multiplication. For preconditioned iterative methods, the preconditioning must be supplied by the user, again in two phases: setup and solve. While there is no default choice of preconditioner analogous to the difference-quotient approximation in the direct case, the references [6, 8], together with the example and demonstration programs included with CVODE, offer considerable assistance in building preconditioners.

Each CVODE linear solver interface consists of four primary phases, devoted to (1) memory allocation and initialization, (2) setup of the matrix data involved, (3) solution of the system, and (4) freeing of memory. The setup and solution phases are separate because the evaluation of Jacobians and preconditioners is done only periodically during the integration, and only as required to achieve convergence.

(a) Directory structure of the SUNDIALS source tree

(b) Directory structure of the SUNDIALS examples

Figure 3.2: Organization of the SUNDIALS suite

24 Code Organization

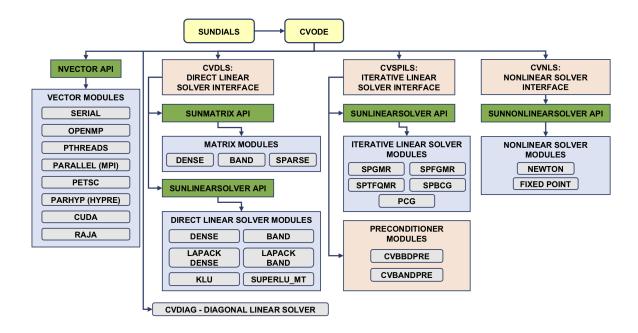

Figure 3.3: Overall structure diagram of the CVODE package. Modules specific to CVODE begin with "CV" (CVDLS, CVDIAG, CVSPILS, CVBBDPRE, CVBANDPRE, and CVNLS), all other items correspond to generic solver and auxiliary modules. Note also that the LAPACK, KLU and SUPERLUMT support is through interfaces to external packages. Users will need to download and compile those packages independently.

CVODE also provides two preconditioner modules, for use with any of the Krylov iterative linear solvers. The first one, CVBANDPRE, is intended to be used with NVECTOR_SERIAL, NVECTOR_OPENMP or NVECTOR_PTHREADS and provides a banded difference-quotient Jacobian-based preconditioner, with corresponding setup and solve routines. The second preconditioner module, CVBBDPRE, works in conjunction with NVECTOR_PARALLEL and generates a preconditioner that is a block-diagonal matrix with each block being a banded matrix.

All state information used by CVODE to solve a given problem is saved in a structure, and a pointer to that structure is returned to the user. There is no global data in the CVODE package, and so, in this respect, it is reentrant. State information specific to the linear solver is saved in a separate structure, a pointer to which resides in the CVODE memory structure. The reentrancy of CVODE was motivated by the anticipated multicomputer extension, but is also essential in a uniprocessor setting where two or more problems are solved by intermixed calls to the package from within a single user program.

Chapter 4

Using CVODE for C Applications

This chapter is concerned with the use of CVODE for the solution of initial value problems (IVPs) in a C language setting. The following sections treat the header files and the layout of the user's main program, and provide descriptions of the CVODE user-callable functions and user-supplied functions.

The sample programs described in the companion document [27] may also be helpful. Those codes may be used as templates (with the removal of some lines used in testing) and are included in the CVODE package.

Users with applications written in FORTRAN should see Chapter 5, which describes the FORTRAN/C interface module.

The user should be aware that not all SUNLINSOL and SUNMATRIX modules are compatible with all NVECTOR implementations. Details on compatability are given in the documentation for each SUNMATRIX module (Chapter 7) and each SUNLINSOL module (Chapter 8). For example, NVECTOR_PARALLEL is not compatible with the dense, banded, or sparse SUNMATRIX types, or with the corresponding dense, banded, or sparse SUNLINSOL modules. Please check Chapters 7 and 8 to verify compatability between these modules. In addition to that documentation, we note that the CVBAND-PRE preconditioning module is only compatible with the NVECTOR_SERIAL, NVECTOR_OPENMP, and NVECTOR_PTHREADS vector implementations, and the preconditioner module CVBBDPRE can only be used with NVECTOR_PARALLEL. It is not recommended to use a threaded vector module with SuperLU_MT unless it is the NVECTOR_OPENMP module, and SuperLU_MT is also compiled with OpenMP.

CVODE uses various constants for both input and output. These are defined as needed in this chapter, but for convenience are also listed separately in Appendix B.

4.1 Access to library and header files

At this point, it is assumed that the installation of CVODE, following the procedure described in Appendix A, has been completed successfully.

Regardless of where the user's application program resides, its associated compilation and load commands must make reference to the appropriate locations for the library and header files required by CVODE. The relevant library files are

- libdir/libsundials_cvode.lib,
- libdir/libsundials_nvec*. lib (one to four files),

where the file extension .lib is typically .so for shared libraries and .a for static libraries. The relevant header files are located in the subdirectories

- *incdir*/include/cvode
- incdir/include/sundials

- incdir/include/nvector
- incdir/include/sunmatrix
- incdir/include/sunlinsol
- incdir/include/sunnonlinsol

The directories *libdir* and *incdir* are the install library and include directories, respectively. For a default installation, these are *instdir*/lib and *instdir*/include, respectively, where *instdir* is the directory where SUNDIALS was installed (see Appendix A).

4.2 Data Types

The sundials_types.h file contains the definition of the type realtype, which is used by the SUNDIALS solvers for all floating-point data, the definition of the integer type sunindextype, which is used for vector and matrix indices, and booleantype, which is used for certain logic operations within SUNDIALS.

4.2.1 Floating point types

The type realtype can be float, double, or long double, with the default being double. The user can change the precision of the SUNDIALS solvers arithmetic at the configuration stage (see $\S A.1.2$).

Additionally, based on the current precision, sundials_types.h defines BIG_REAL to be the largest value representable as a realtype, SMALL_REAL to be the smallest value representable as a realtype, and UNIT_ROUNDOFF to be the difference between 1.0 and the minimum realtype greater than 1.0.

Within SUNDIALS, real constants are set by way of a macro called RCONST. It is this macro that needs the ability to branch on the definition realtype. In ANSI C, a floating-point constant with no suffix is stored as a double. Placing the suffix "F" at the end of a floating point constant makes it a float, whereas using the suffix "L" makes it a long double. For example,

```
#define A 1.0
#define B 1.0F
#define C 1.0L
```

defines A to be a double constant equal to 1.0, B to be a float constant equal to 1.0, and C to be a long double constant equal to 1.0. The macro call RCONST(1.0) automatically expands to 1.0 if realtype is double, to 1.0F if realtype is float, or to 1.0L if realtype is long double. SUNDIALS uses the RCONST macro internally to declare all of its floating-point constants.

A user program which uses the type realtype and the RCONST macro to handle floating-point constants is precision-independent except for any calls to precision-specific standard math library functions. (Our example programs use both realtype and RCONST.) Users can, however, use the type double, float, or long double in their code (assuming that this usage is consistent with the typedef for realtype). Thus, a previously existing piece of ANSI C code can use SUNDIALS without modifying the code to use realtype, so long as the SUNDIALS libraries use the correct precision (for details see §A.1.2).

4.2.2 Integer types used for vector and matrix indices

The type sunindextype can be either a 32- or 64-bit signed integer. The default is the portable int64_t type, and the user can change it to int32_t at the configuration stage. The configuration system will detect if the compiler does not support portable types, and will replace int32_t and int64_t with int and long int, respectively, to ensure use of the desired sizes on Linux, Mac OS X, and Windows platforms. SUNDIALS currently does not support unsigned integer types for vector and matrix indices, although these could be added in the future if there is sufficient demand.

4.3 Header files 27

A user program which uses sunindextype to handle vector and matrix indices will work with both index storage types except for any calls to index storage-specific external libraries. (Our C and C++ example programs use sunindextype.) Users can, however, use any one of int, long int, int32_t, int64_t or long long int in their code, assuming that this usage is consistent with the typedef for sunindextype on their architecture). Thus, a previously existing piece of ANSI C code can use SUNDIALS without modifying the code to use sunindextype, so long as the SUNDIALS libraries use the appropriate index storage type (for details see §A.1.2).

4.3 Header files

The calling program must include several header files so that various macros and data types can be used. The header file that is always required is:

• cvode/cvode.h, the main header file for CVODE, which defines the several types and various constants, and includes function prototypes.

Note that cvode.h includes sundials_types.h, which defines the types realtype, sunindextype, and booleantype and the constants SUNFALSE and SUNTRUE.

The calling program must also include a NVECTOR implementation header file, of the form nvector/nvector_***.h. See Chapter 6 for the appropriate name. This file in turn includes the header file sundials_nvector.h which defines the abstract N_Vector data type.

If using a non-default nonlinear solver module, or when interacting with a SUNNONLINSOL module directly, the calling program must also include a SUNNONLINSOL implementation header file, of the form sunnonlinsol_***.h. See Chapter 9 for the appropriate name. This file in turn includes the header file sundials_nonlinearsolver.h which defines the abstract SUNNonlinearSolver data type.

If using a nonlinear solver that requires the solution of a linear system of the form (2.5) (e.g., the default Newton iteration), then a linear solver module header file will be required. The header files corresponding to the various linear solver interfaces and linear solver modules available for use with CVODE are:

- cvode/cvode_direct.h, which is used with the CVDLS direct linear solver interface to access direct solvers with the following header files:
 - sunlinsol/sunlinsol_dense.h, which is used with the dense linear solver module, SUN-LINSOL_DENSE;
 - sunlinsol/sunlinsol_band.h, which is used with the banded linear solver module, SUN-LINSOL_BAND;
 - sunlinsol/sunlinsol_lapackdense.h, which is used with the LAPACK dense linear solver interface module, SUNLINSOL_LAPACKDENSE;
 - sunlinsol/sunlinsol_lapackband.h, which is used with the LAPACK banded linear solver interface module, SUNLINSOL_LAPACKBAND;
 - sunlinsol/sunlinsol_klu.h, which is used with the KLU sparse linear solver interface module, SUNLINSOL_KLU;
 - sunlinsol/sunlinsol_superlumt.h, which is used with the SUPERLUMT sparse linear solver interface module, SUNLINSOL_SUPERLUMT;
- cvode/cvode_spils.h, which is used with the CVSPILS iterative linear solver interface to access iterative solvers with the following header files:
 - sunlinsol/sunlinsol_spgmr.h, which is used with the scaled, preconditioned GMRES
 Krylov linear solver module, SUNLINSOL_SPGMR;
 - sunlinsol/sunlinsol_spfgmr.h, which is used with the scaled, preconditioned FGMRES Krylov linear solver module, SUNLINSOL_SPFGMR;

- sunlinsol/sunlinsol_spbcgs.h, which is used with the scaled, preconditioned Bi-CGStab Krylov linear solver module, SUNLINSOL_SPBCGS;
- sunlinsol/sunlinsol_sptfqmr.h, which is used with the scaled, preconditioned TFQMR
 Krylov linear solver module, SUNLINSOL_SPTFQMR;
- sunlinsol/sunlinsol_pcg.h, which is used with the scaled, preconditioned CG Krylov linear solver module, SUNLINSOL_PCG;
- cvode/cvode_diag.h, which is used with the CVDIAG diagonal linear solver interface.

The header files for the SUNLINSOL_DENSE and SUNLINSOL_LAPACKDENSE linear solver modules include the file sunmatrix/sunmatrix_dense.h, which defines the SUNMATRIX_DENSE matrix module, as as well as various functions and macros acting on such matrices.

The header files for the SUNLINSOL_BAND and SUNLINSOL_LAPACKBAND linear solver modules include the file sunmatrix/sunmatrix_band.h, which defines the SUNMATRIX_BAND matrix module, as as well as various functions and macros acting on such matrices.

The header files for the SUNLINSOL_KLU and SUNLINSOL_SUPERLUMT sparse linear solvers include the file sunmatrix_sparse.h, which defines the SUNMATRIX_SPARSE matrix module, as well as various functions and macros acting on such matrices.

The header files for the Krylov iterative solvers include the file sundials_iterative.h, which enumerates the kind of preconditioning, and (for the SPGMR and SPFGMR solvers) the choices for the Gram-Schmidt process.

Other headers may be needed, according to the choice of preconditioner, etc. For example, in the cvDiurnal_kry_p example (see [27]), preconditioning is done with a block-diagonal matrix. For this, even though the SUNLINSOL_SPGMR linear solver is used, the header sundials/sundials_dense.h is included for access to the underlying generic dense matrix arithmetic routines.

4.4 A skeleton of the user's main program

The following is a skeleton of the user's main program (or calling program) for the integration of an ODE IVP. Most of the steps are independent of the NVECTOR, SUNMATRIX, and SUNLINSOL implementations used. For the steps that are not, refer to Chapters 6, 7, and 8 for the specific name of the function to be called or macro to be referenced.

1. Initialize parallel or multi-threaded environment, if appropriate

For example, call MPI_Init to initialize MPI if used, or set num_threads, the number of threads to use within the threaded vector functions, if used.

2. Set problem dimensions etc.

This generally includes the problem size N, and may include the local vector length Nlocal.

Note: The variables N and Nlocal should be of type sunindextype.

3. Set vector of initial values

To set the vector y0 of initial values, use the appropriate functions defined by the particular NVECTOR implementation.

For native SUNDIALS vector implementations (except the CUDA and RAJA-based ones), use a call of the form $y0 = N_VMake_***(..., ydata)$ if the realtype array ydata containing the initial values of y already exists. Otherwise, create a new vector by making a call of the form $y0 = N_VMew_***(...)$, and then set its elements by accessing the underlying data with a call of the form ydata = $N_VGetArrayPointer(y0)$. See §6.1-6.4 for details.

For the hypre and PETSc vector wrappers, first create and initialize the underlying vector, and then create an NVECTOR wrapper with a call of the form y0 = N_VMake_***(yvec), where yvec

is a hypre or PETSc vector. Note that calls like N_VNew_***(...) and N_VGetArrayPointer(...) are not available for these vector wrappers. See §6.5 and §6.6 for details.

If using either the CUDA- or RAJA-based vector implementations use a call of the form y0 = N_VMake_***(..., c) where c is a pointer to a suncudavec or sunrajavec vector class if this class already exists. Otherwise, create a new vector by making a call of the form y0 = N_VNew_***(...), and then set its elements by accessing the underlying data where it is located with a call of the form N_VGetDeviceArrayPointer_*** or N_VGetHostArrayPointer_***. Note that the vector class will allocate memory on both the host and device when instantiated. See §6.7-6.8 for details.

4. Create CVODE object

Call cvode_mem = CVodeCreate(lmm) to create the CVODE memory block and to specify the solution method (linear multistep method). CVodeCreate returns a pointer to the CVODE memory structure. See §4.5.1 for details.

5. Initialize CVODE solver

Call CVodeInit(...) to provide required problem specifications, allocate internal memory for CVODE, and initialize CVODE. CVodeInit returns a flag, the value of which indicates either success or an illegal argument value. See §4.5.1 for details.

6. Specify integration tolerances

Call CVodeSStolerances(...) or CVodeSVtolerances(...) to specify either a scalar relative tolerance and scalar absolute tolerance, or a scalar relative tolerance and a vector of absolute tolerances, respectively. Alternatively, call CVodeWFtolerances to specify a function which sets directly the weights used in evaluating WRMS vector norms. See §4.5.2 for details.

7. Set optional inputs

Call CVodeSet* functions to change any optional inputs that control the behavior of CVODE from their default values. See §4.5.7.1 for details.

8. Create matrix object

If a nonlinear solver requiring a linear solve will be used (e.g., the the default Newton iteration) and the linear solver will be a direct linear solver, then a template Jacobian matrix must be created by calling the appropriate constructor function defined by the particular SUNMATRIX implementation.

NOTE: The dense, banded, and sparse matrix objects are usable only in a serial or threaded environment.

9. Create linear solver object

If a nonlinear solver requiring a linear solver is chosen (e.g., the default Newton iteration), then the desired linear solver object must be created by calling the appropriate constructor function defined by the particular SUNLINSOL implementation.

10. Set linear solver optional inputs

Call *Set* functions from the selected linear solver module to change optional inputs specific to that linear solver. See the documentation for each SUNLINSOL module in Chapter 8 for details.

11. Attach linear solver module

If a nonlinear solver requiring a linear solver is chosen (e.g., the default Newton iteration), then initialize the CVDLS or CVSPILS linear solver interface by attaching the linear solver object (and matrix object, if applicable) with one of the following calls (for details see §4.5.3):

```
ier = CVDlsSetLinearSolver(...);
ier = CVSpilsSetLinearSolver(...);
```

Alternately, if the CVODE-specific diagonal linear solver module, CVDIAG, is desired, initialize the linear solver module and attach it to CVODE with the call

```
ier = CVDiag(...);
```

12. Set linear solver interface optional inputs

Call CVDlsSet* or CVSpilsSet* functions to change optional inputs specific to that linear solver interface. See §4.5.7 for details.

13. Create nonlinear solver object (optional)

If using a non-default nonlinear solver, then create the desired nonlinear solver object by calling the appropriate constructor function defined by the particular SUNNONLINSOL implementation (e.g., NLS = SUNNonlinSol_****(...); where *** is the name of the nonlinear solver (see Chapter 9 for details).

14. Attach nonlinear solver module (optional)

If using a non-default nonlinear solver, then initialize the CVNLS nonlinear solver interface by attaching the nonlinear solver object by calling ier = CVodeSetNonlinearSolver(cvode_mem, NLS);

15. Set nonlinear solver optional inputs (optional)

Call the appropriate set functions for the selected nonlinear solver module to change optional inputs specific to that nonlinear solver. These *must* be called after CVodeInit if using the default nonlinear solver or after attaching a new nonlinear solver to CVODE, otherwise the optional inputs will be overridden by CVODE defaults. See Chapter 9 for more information on optional inputs.

16. Specify rootfinding problem

Optionally, call CVodeRootInit to initialize a rootfinding problem to be solved during the integration of the ODE system. See §4.5.5, and see §4.5.7.4 for relevant optional input calls.

17. Advance solution in time

For each point at which output is desired, call ier = CVode(cvode_mem, tout, yout, &tret, itask). Here itask specifies the return mode. The vector yout (which can be the same as the vector y0 above) will contain y(t). See §4.5.6 for details.

18. Get optional outputs

Call CV*Get* functions to obtain optional output. See §4.5.9 for details.

19. Deallocate memory for solution vector

Upon completion of the integration, deallocate memory for the vector y (or yout) by calling the appropriate destructor function defined by the NVECTOR implementation:

```
N_VDestroy(y);
```

20. Free solver memory

Call CVodeFree (&cvode_mem) to free the memory allocated by CVODE.

21. Free nonlinear solver memory (optional)

If a non-default nonlinear solver was used, then call SUNNonlinSolFree(NLS) to free any memory allocated for the SUNNONLINSOL object.

22. Free linear solver and matrix memory

Call SUNLinSolFree and SUNMatDestroy to free any memory allocated for the linear solver and matrix objects created above.

23. Finalize MPI, if used

Call MPI_Finalize() to terminate MPI.

SUNDIALS provides some linear solvers only as a means for users to get problems running and not as highly efficient solvers. For example, if solving a dense system, we suggest using the LAPACK solvers if the size of the linear system is > 50,000. (Thanks to A. Nicolai for his testing and recommendation.) Table 4.1 shows the linear solver interfaces available as SUNLINSOL modules and the vector implementations required for use. As an example, one cannot use the dense direct solver interfaces with the MPI-based vector implementation. However, as discussed in Chapter 8 the SUNDIALS packages operate on generic SUNLINSOL objects, allowing a user to develop their own solvers should they so desire.

Table 4.1: SUNDIALS linear solver interfaces and vector implementations that can be used for each.

4.5 User-callable functions

This section describes the CVODE functions that are called by the user to setup and then solve an IVP. Some of these are required. However, starting with §4.5.7, the functions listed involve optional inputs/outputs or restarting, and those paragraphs may be skipped for a casual use of CVODE. In any case, refer to §4.4 for the correct order of these calls.

On an error, each user-callable function returns a negative value and sends an error message to the error handler routine, which prints the message on **stderr** by default. However, the user can set a file as error output or can provide his own error handler function (see §4.5.7.1).

4.5.1 CVODE initialization and deallocation functions

The following three functions must be called in the order listed. The last one is to be called only after the IVP solution is complete, as it frees the CVODE memory block created and allocated by the first two calls.

CVodeCreate

Description The function CVodeCreate instantiates a CVODE solver object and specifies the solution method.

The recommended choices for lmm are CV_ADAMS for nonstiff problems and CV_BDF for stiff problems. The default Newton iteration is recommended for stiff problems, and the fixed-point solver (previously referred to as the functional iteration in this guide) is recommended for nonstiff problems. For details on how to attach a different nonlinear solver module to CVODE see the description of CvodeSetNonlinearSolver.

Return value If successful, CVodeCreate returns a pointer to the newly created CVODE memory block (of type void *). Otherwise, it returns NULL.

CVodeInit

Call flag = CVodeInit(cvode_mem, f, t0, y0);

 $\label{problem} \textbf{Description} \quad \text{The function $\tt CVodeInit$ provides required problem and solution specifications, allocates}$

internal memory, and initializes CVODE.

Arguments cvode_mem (void *) pointer to the CVODE memory block returned by CVodeCreate.

f (CVRhsFn) is the C function which computes the right-hand side function f in the ODE. This function has the form f(t, y, ydot, user_data) (for full details see §4.6.1).

t0 (realtype) is the initial value of t. y0 (N_Vector) is the initial value of y.

Return value The return value flag (of type int) will be one of the following:

CV_SUCCESS The call to CVodeInit was successful.

CV_MEM_NULL The CVODE memory block was not initialized through a previous call to CVodeCreate.

CV_MEM_FAIL A memory allocation request has failed.

CV_ILL_INPUT An input argument to CVodeInit has an illegal value.

Notes If an error occurred, CVodeInit also sends an error message to the error handler function.

CVodeFree

Call CVodeFree(&cvode_mem);

Description The function CVodeFree frees the memory allocated by a previous call to CVodeCreate.

Arguments The argument is the pointer to the CVODE memory block (of type void *).

Return value The function CVodeFree has no return value.

4.5.2 CVODE tolerance specification functions

One of the following three functions must be called to specify the integration tolerances (or directly specify the weights used in evaluating WRMS vector norms). Note that this call must be made after the call to CVodeInit.

CVodeSStolerances

Call flag = CVodeSStolerances(cvode_mem, reltol, abstol);

Description The function CVodeSStolerances specifies scalar relative and absolute tolerances.

Arguments cvode_mem (void *) pointer to the CVODE memory block returned by CVodeCreate.

reltol (realtype) is the scalar relative error tolerance.
abstol (realtype) is the scalar absolute error tolerance.

Return value The return value flag (of type int) will be one of the following:

CV_SUCCESS The call to CVodeSStolerances was successful.

CV_MEM_NULL The CVODE memory block was not initialized through a previous call to CVodeCreate.

CV_NO_MALLOC The allocation function CVodeInit has not been called.

CV_ILL_INPUT One of the input tolerances was negative.

CVodeSVtolerances

Call flag = CVodeSVtolerances(cvode_mem, reltol, abstol);

Description The function CVodeSVtolerances specifies scalar relative tolerance and vector absolute

tolerances.

Arguments cvode_mem (void *) pointer to the CVODE memory block returned by CVodeCreate.

reltol (realtype) is the scalar relative error tolerance.

abstol (N_Vector) is the vector of absolute error tolerances.

Return value The return value flag (of type int) will be one of the following:

CV_SUCCESS The call to CVodeSVtolerances was successful.

CV_MEM_NULL The CVODE memory block was not initialized through a previous call to

 ${\tt CVodeCreate}.$

 ${\tt CV_NO_MALLOC}$ The allocation function ${\tt CVodeInit}$ has not been called.

CV_ILL_INPUT The relative error tolerance was negative or the absolute tolerance had

a negative component.

Notes This choice of tolerances is important when the absolute error tolerance needs to be different for each component of the state vector y.

CVodeWFtolerances

Call flag = CVodeWFtolerances(cvode_mem, efun);

Description The function CVodeWFtolerances specifies a user-supplied function efun that sets the multiplicative error weights W_i for use in the weighted RMS norm, which are normally

defined by Eq. (2.7).

Arguments cvode_mem (void *) pointer to the CVODE memory block returned by CVodeCreate.

efun (CVEwtFn) is the C function which defines the ewt vector (see §4.6.3).

Return value The return value flag (of type int) will be one of the following:

CV_SUCCESS The call to CVodeWFtolerances was successful.

CV_MEM_NULL The CVODE memory block was not initialized through a previous call to CVodeCreate.

CV_NO_MALLOC The allocation function CVodeInit has not been called.

General advice on choice of tolerances. For many users, the appropriate choices for tolerance values in reltol and abstol are a concern. The following pieces of advice are relevant.

- (1) The scalar relative tolerance reltol is to be set to control relative errors. So reltol = 10^{-4} means that errors are controlled to .01%. We do not recommend using reltol larger than 10^{-3} . On the other hand, reltol should not be so small that it is comparable to the unit roundoff of the machine arithmetic (generally around 1.0E-15).
- (2) The absolute tolerances abstol (whether scalar or vector) need to be set to control absolute errors when any components of the solution vector y may be so small that pure relative error control is meaningless. For example, if y[i] starts at some nonzero value, but in time decays to zero, then pure relative error control on y[i] makes no sense (and is overly costly) after y[i] is below some noise level. Then abstol (if scalar) or abstol[i] (if a vector) needs to be set to that noise level. If

the different components have different noise levels, then abstol should be a vector. See the example cvRoberts_dns in the CVODE package, and the discussion of it in the CVODE Examples document [27]. In that problem, the three components vary betwen 0 and 1, and have different noise levels; hence the abstol vector. It is impossible to give any general advice on abstol values, because the appropriate noise levels are completely problem-dependent. The user or modeler hopefully has some idea as to what those noise levels are.

(3) Finally, it is important to pick all the tolerance values conservatively, because they control the error committed on each individual time step. The final (global) errors are some sort of accumulation of those per-step errors. A good rule of thumb is to reduce the tolerances by a factor of .01 from the actual desired limits on errors. So if you want .01% accuracy (globally), a good choice is reltol = 10^{-6} . But in any case, it is a good idea to do a few experiments with the tolerances to see how the computed solution values vary as tolerances are reduced.

Advice on controlling unphysical negative values. In many applications, some components in the true solution are always positive or non-negative, though at times very small. In the numerical solution, however, small negative (hence unphysical) values can then occur. In most cases, these values are harmless, and simply need to be controlled, not eliminated. The following pieces of advice are relevant.

- (1) The way to control the size of unwanted negative computed values is with tighter absolute tolerances. Again this requires some knowledge of the noise level of these components, which may or may not be different for different components. Some experimentation may be needed.
- (2) If output plots or tables are being generated, and it is important to avoid having negative numbers appear there (for the sake of avoiding a long explanation of them, if nothing else), then eliminate them, but only in the context of the output medium. Then the internal values carried by the solver are unaffected. Remember that a small negative value in y returned by CVODE, with magnitude comparable to abstol or less, is equivalent to zero as far as the computation is concerned.
- (3) The user's right-hand side routine f should never change a negative value in the solution vector f to a non-negative value, as a "solution" to this problem. This can cause instability. If the f routine cannot tolerate a zero or negative value (e.g. because there is a square root or log of it), then the offending value should be changed to zero or a tiny positive number in a temporary variable (not in the input f vector) for the purposes of computing f (f, f).
- (4) Positivity and non-negativity constraints on components can be enforced by use of the recoverable error return feature in the user-supplied right-hand side function. However, because this option involves some extra overhead cost, it should only be exercised if the use of absolute tolerances to control the computed values is unsuccessful.

4.5.3 Linear solver interface functions

As previously explained, if the nonlinear solver requires the solution of linear systems of the form (2.5) (e.g., the default Newton iteration), there are three CVODE linear solver interfaces currently available for this task: CVDLS, CVDIAG and CVSPILS.

The first corresponds to the use of Direct Linear Solvers, and utilizes SUNMATRIX objects to store the Jacobian $J = \partial f/\partial y$, the matrix $M = I - \gamma J$, and factorizations used throughout the solution process.

The CVDIAG linear solver is also a direct linear solver, but it only uses a diagonal approximation to J.

The third corresponds to the use of Scaled, Preconditioned, Iterative Linear Solvers, utilizing matrix-free Krylov methods to solve the linear systems of equations. With most of these methods, preconditioning can be done on the left only, on the right only, on both the left and the right, or not at all. The exceptions to this rule are specification of a preconditioning only and PCG that performs symmetric preconditioning. For the specification of a preconditioner, see the iterative linear solver sections in §4.5.7 and §4.6.

If preconditioning is done, user-supplied functions define left and right preconditioner matrices P_1 and P_2 (either of which could be the identity matrix), such that the product P_1P_2 approximates the

```
matrix M = I - \gamma J of (2.6).
```

To specify a generic linear solver to CVODE, after the call to CVodeCreate but before any calls to CVode, the user's program must create the appropriate SUNLINSOL object and call either of the functions CVDlsSetLinearSolver or CVSpilsSetLinearSolver, as documented below. The first argument passed to these functions is the CVODE memory pointer returned by CVodeCreate; the second argument passed to these functions is the desired SUNLINSOL object to use for solving linear systems. A call to one of these functions initializes the appropriate CVODE linear solver interface, linking this to the main CVODE integrator, and allows the user to specify parameters which are specific to a particular solver interface. The use of each of the generic linear solvers involves certain constants and possibly some macros, that are likely to be needed in the user code. These are available in the corresponding header file associated with the specific SUNMATRIX or SUNLINSOL module in question, as described in Chapters 7 and 8.

To instead specify the CVODE-specific diagonal linear solver interface, the user's program must call CVDiag, as documented below. The first argument passed to this function is the CVODE memory pointer returned by CVodeCreate.

CVDlsSetLinearSolver

Call flag = CVDlsSetLinearSolver(cvode_mem, LS, J);

Description

The function CVDlsSetLinearSolver attaches a direct SUNLINSOL object LS and corresponding template Jacobian SUNMATRIX object J to CVODE, initializing the CVDLS direct linear solver interface.

The user's main program must include the cvode_direct.h header file.

Arguments

cvode_mem (void *) pointer to the CVODE memory block.

LS (SUNLinearSolver) SUNLINSOL object to use for solving linear systems of the form (2.5).

J (SUNMATRIX object for used as a template for the Jacobian (must have a type compatible with the linear solver object).

Return value The return value flag (of type int) is one of

CVDLS_SUCCESS The CVDLS initialization was successful.

CVDLS_MEM_NULL The cvode_mem pointer is NULL.

CVDLS_ILL_INPUT The CVDLS solver is not compatible with the LS or J input objects or is incompatible with the current NVECTOR module.

CVDLS_MEM_FAIL A memory allocation request failed.

Notes

The CVDLS linear solver interface is not compatible with all implementations of the SUN-LINSOL and NVECTOR modules. Specifically, CVDLS requires use of a *direct* SUNLINSOL object and a serial or theaded NVECTOR module. Additional compatibility limitations for each SUNLINSOL object (i.e. SUNMATRIX and NVECTOR object compatibility) are described in Chapter 8.

CVSpilsSetLinearSolver

Call flag = CVSpilsSetLinearSolver(cvode_mem, LS);

Description The function CVSpilsSetLinearSolver attaches an iterative SUNLINSOL object LS to CVODE, initializing the CVSPILS scaled, preconditioned, iterative linear solver interface.

The user's main program must include the cvode_spils.h header file.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

LS (SUNLinearSolver) SUNLINSOL object to use for solving linear systems of the form (2.5).

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The CVSPILS initialization was successful.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_ILL_INPUT The CVSPILS solver is not compatible with the LS object or is incompatible with the current NVECTOR module.

CVSPILS_MEM_FAIL A memory allocation request failed.

CVSPILS_SUNLS_FAIL A call to the LS object failed.

Notes

The CVSPILS linear solver interface is not compatible with all implementations of the SUNLINSOL and NVECTOR modules. Specifically, CVSPILS requires use of an *iterative* SUNLINSOL object. Additional compatibility limitations for each SUNLINSOL object (i.e. required NVECTOR routines) are described in Chapter 8.

CVDiag

Call flag = CVDiag(cvode_mem);

Description The function CVDiag selects the CVDIAG linear solver.

The user's main program must include the cvode_diag.h header file.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

Return value The return value flag (of type int) is one of:

CVDIAG_SUCCESS The CVDIAG initialization was successful.

CVDIAG_MEM_NULL The cvode_mem pointer is NULL.

 ${\tt CVDIAG_ILL_INPUT\ The\ CVDIAG\ solver\ is\ not\ compatible\ with\ the\ current\ NVECTOR}$

module.

CVDIAG_MEM_FAIL A memory allocation request failed.

Notes

The CVDIAG solver is the simplest of all of the current CVODE linear solver interfaces. The CVDIAG solver uses an approximate diagonal Jacobian formed by way of a difference quotient. The user does *not* have the option of supplying a function to compute an approximate diagonal Jacobian.

4.5.4 Nonlinear solver interface function

By default CVODE uses the SUNNONLINSOL implementation of Newton's method defined by the SUNNONLINSOL_NEWTON module (see §9.2). To specify a different nonlinear solver in CVODE, the user's program must create a SUNNONLINSOL object by calling the appropriate constructor routine and attach the SUNNONLINSOL object by calling CVodeSetNonlinearSolver, as documented below.

When changing the nonlinear solve in CVODE, CVodeSetNonlinearSolver must be called after CVodeInit. If any calls to CVode have been made, then CVODE will need to be reinitialized by calling CVodeReInit to ensure the nonlinear solver is initialized correctly before any subsequent calls to CVode.

The first argument passed to CVodeSetNonlinearSolver is the CVODE memory pointer returned by CVodeCreate and the second argument is the SUNNONLINSOL object to use for solving the nonlinear system (2.3) or (2.4). A call to this function attaches the nonlinear solver to the main CVODE integrator.

CVodeSetNonlinearSolver

Call flag = CVodeSetNonlinearSolver(cvode_mem, NLS);

Description The function CVodeSetNonLinearSolver attaches a SUNNONLINSOL object (NLS) to

CVODE.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

LS (SUNNonlinearSolver) SUNNONLINSOL object to use for solving nonlinear systems (2.3) or (2.4).

Return value The return value flag (of type int) is one of

CV_SUCCESS The nonlinear solver was successfully attached.

CV_MEM_NULL The cvode_mem pointer is NULL.

CV_ILL_INPUT The SUNNONLINSOL object is NULL, does not implement the required nonlinear solver operations, is not of the correct type, or the residual function, convergence test function, or maximum number of nonlinear iterations could not be set.

4.5.5 Rootfinding initialization function

While solving the IVP, CVODE has the capability to find the roots of a set of user-defined functions. To activate the root finding algorithm, call the following function. This is normally called only once, prior to the first call to CVode, but if the rootfinding problem is to be changed during the solution, CVodeRootInit can also be called prior to a continuation call to CVode.

CVodeRootInit

Call flag = CVodeRootInit(cvode_mem, nrtfn, g);

Description The function CVodeRootInit specifies that the roots of a set of functions $g_i(t,y)$ are to

be found while the IVP is being solved.

Arguments cvode_mem (void *) pointer to the CVODE memory block returned by CVodeCreate.

nrtfn (int) is the number of root functions q_i .

g (CVRootFn) is the C function which defines the nrtfn functions $g_i(t,y)$

whose roots are sought. See $\S4.6.4$ for details.

Return value The return value flag (of type int) is one of

CV_SUCCESS The call to CVodeRootInit was successful.

CV_MEM_NULL The cvode_mem argument was NULL.

CV_MEM_FAIL A memory allocation failed.

CV_ILL_INPUT The function g is NULL, but nrtfn > 0.

Notes If a new IVP is to be solved with a call to CVodeReInit, where the new IVP has no rootfinding problem but the prior one did, then call CVodeRootInit with nrtfn= 0.

4.5.6 CVODE solver function

This is the central step in the solution process — the call to perform the integration of the IVP. One of the input arguments (itask) specifies one of two modes as to where CVODE is to return a solution. But these modes are modified if the user has set a stop time (with CVodeSetStopTime) or requested rootfinding.

CVode

Call flag = CVode(cvode_mem, tout, yout, &tret, itask);

Description The function CVode integrates the ODE over an interval in t.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

tout (realtype) the next time at which a computed solution is desired.

yout (N_Vector) the computed solution vector.

tret (realtype) the time reached by the solver (output).

itask (int) a flag indicating the job of the solver for the next user step. The CV_NORMAL option causes the solver to take internal steps until it has reached or just passed the user-specified tout parameter. The solver then interpolates in order to return an approximate value of y(tout). The CV_ONE_STEP

option tells the solver to take just one internal step and then return the solution at the point reached by that step.

Return value CVode returns a vector yout and a corresponding independent variable value t = tret, such that yout is the computed value of y(t).

In CV_NORMAL mode (with no errors), tret will be equal to tout and yout = y(tout).

The return value flag (of type int) will be one of the following:

CV_SUCCESS CVode succeeded and no roots were found.

CV_TSTOP_RETURN CVode succeeded by reaching the stopping point specified through

the optional input function CVodeSetStopTime (see §4.5.7.1).

 ${\tt CV_ROOT_RETURN} \quad {\tt CVode} \ {\tt succeeded} \ {\tt and} \ {\tt found} \ {\tt one} \ {\tt or} \ {\tt more} \ {\tt roots}. \ {\tt In} \ {\tt this} \ {\tt case}, \ {\tt tret} \ {\tt is}$

the location of the root. If $\mathtt{nrtfn} > 1$, call $\mathtt{CVodeGetRootInfo}$ to

see which g_i were found to have a root.

CV_MEM_NULL The cvode_mem argument was NULL.

CV_NO_MALLOC The CVODE memory was not allocated by a call to CVodeInit.

CV_ILL_INPUT One of the inputs to CVode was illegal, or some other input to the

solver was either illegal or missing. The latter category includes the following situations: (a) The tolerances have not been set. (b) A component of the error weight vector became zero during internal time-stepping. (c) The linear solver initialization function (called by the user after calling CVodeCreate) failed to set the linear solver-specific lsolve field in cvode_mem. (d) A root of one of the root functions was found both at a point t and also very near t. In any case, the user should see the error message for details.

CV_TOO_CLOSE The initial time t_0 and the final time t_{out} are too close to each other

and the user did not specify an initial step size.

CV_TOO_MUCH_WORK The solver took mxstep internal steps but still could not reach tout.

The default value for mxstep is MXSTEP_DEFAULT = 500.

The galven could not gotisfy the accuracy demanded by the

CV_TOO_MUCH_ACC The solver could not satisfy the accuracy demanded by the user for some internal step.

CV_ERR_FAILURE Either error test failures occurred too many times (MXNEF = 7) during one internal time step, or with $|h| = h_{min}$.

CV_CONV_FAILURE Either convergence test failures occurred too many times (MXNCF =

10) during one internal time step, or with $|h| = h_{min}$.

CV_LINIT_FAIL The linear solver's initialization function failed.

CV_LSETUP_FAIL The linear solver's setup function failed in an unrecoverable manner.

 ${\tt CV_LSOLVE_FAIL} \qquad \text{The linear solver's solve function failed in an unrecoverable manner}.$

CV_RHSFUNC_FAIL The right-hand side function failed in an unrecoverable manner.

CV_FIRST_RHSFUNC_FAIL The right-hand side function had a recoverable error at the first call.

CV_REPTD_RHSFUNC_ERR Convergence test failures occurred too many times due to repeated recoverable errors in the right-hand side function. This flag will also be returned if the right-hand side function had repeated recoverable errors during the estimation of an initial step size.

CV_UNREC_RHSFUNC_ERR The right-hand function had a recoverable error, but no recovery was possible. This failure mode is rare, as it can occur only if the right-hand side function fails recoverably after an error test failed while at order one.

CV_RTFUNC_FAIL The rootfinding function failed.

The vector yout can occupy the same space as the vector you of initial conditions that was passed to CVodeInit.

Notes

Optional input	Function name	Default					
CVODE main solver							
Pointer to an error file	CVodeSetErrFile	stderr					
Error handler function	CVodeSetErrHandlerFn	internal fn.					
User data	CVodeSetUserData	NULL					
Maximum order for BDF method	CVodeSetMaxOrd	5					
Maximum order for Adams method	CVodeSetMaxOrd	12					
Maximum no. of internal steps before t_{out}	CVodeSetMaxNumSteps	500					
Maximum no. of warnings for $t_n + h = t_n$	CVodeSetMaxHnilWarns	10					
Flag to activate stability limit detection	CVodeSetStabLimDet	SUNFALSE					
Initial step size	CVodeSetInitStep	estimated					
Minimum absolute step size	CVodeSetMinStep	0.0					
Maximum absolute step size	CVodeSetMaxStep	∞					
Value of t_{stop}	CVodeSetStopTime	undefined					
Maximum no. of error test failures	CVodeSetMaxErrTestFails	7					
Maximum no. of nonlinear iterations	CVodeSetMaxNonlinIters	3					
Maximum no. of convergence failures	CVodeSetMaxConvFails	10					
Coefficient in the nonlinear convergence test	CVodeSetNonlinConvCoef	0.1					
Direction of zero-crossing	CVodeSetRootDirection	both					
Disable rootfinding warnings	CVodeSetNoInactiveRootWarn	none					
CVDLS linear solver interface							
Jacobian function	CVDlsSetJacFn	DQ					
CVSPILS linear solver interface							
Preconditioner functions	CVSpilsSetPreconditioner	NULL, NULL					
Jacobian-times-vector functions	CVSpilsSetJacTimes	NULL, DQ					
Ratio between linear and nonlinear tolerances	CVSpilsSetEpsLin	0.05					

Table 4.2: Optional inputs for CVODE, CVDLS, and CVSPILS

In the CV_ONE_STEP mode, tout is used only on the first call, and only to get the direction and a rough scale of the independent variable.

All failure return values are negative and so the test flag < 0 will trap all CVode failures.

On any error return in which one or more internal steps were taken by CVode, the returned values of tret and yout correspond to the farthest point reached in the integration. On all other error returns, tret and yout are left unchanged from the previous CVode return.

4.5.7 Optional input functions

There are numerous optional input parameters that control the behavior of the CVODE solver. CVODE provides functions that can be used to change these optional input parameters from their default values. Table 4.2 lists all optional input functions in CVODE which are then described in detail in the remainder of this section, beginning with those for the main CVODE solver and continuing with those for the linear solver interfaces. Note that the diagonal linear solver module has no optional inputs. For the most casual use of CVODE, the reader can skip to §4.6.

We note that, on an error return, all of the optional input functions send an error message to the error handler function. We also note that all error return values are negative, so the test flag < 0 will catch all errors.

4.5.7.1 Main solver optional input functions

The calls listed here can be executed in any order. However, if either of the functions CVodeSetErrFile or CVodeSetErrHandlerFn is to be called, that call should be first, in order to take effect for any later error message.

CVodeSetErrFile

Call flag = CVodeSetErrFile(cvode_mem, errfp);

Description The function CVodeSetErrFile specifies a pointer to the file where all CVODE messages

should be directed when the default CVODE error handler function is used.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

errfp (FILE *) pointer to output file.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes The default value for errfp is stderr.

Passing a value of NULL disables all future error message output (except for the case in which the CVODE memory pointer is NULL). This use of CVodeSetErrFile is strongly discouraged.

If CVodeSetErrFile is to be called, it should be called before any other optional input functions, in order to take effect for any later error message.

⚠

CVodeSetErrHandlerFn

Call flag = CVodeSetErrHandlerFn(cvode_mem, ehfun, eh_data);

Description The function CVodeSetErrHandlerFn specifies the optional user-defined function to be

used in handling error messages.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

ehfun (CVErrHandlerFn) is the C error handler function (see §4.6.2).

eh_data (void *) pointer to user data passed to ehfun every time it is called.

Return value The return value flag (of type int) is one of

CV_SUCCESS The function enfun and data pointer eh_data have been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes Error messages indicating that the CVODE solver memory is NULL will always be directed

to stderr.

CVodeSetUserData

Call flag = CVodeSetUserData(cvode_mem, user_data);

Description The function CVodeSetUserData specifies the user data block user_data and attaches

it to the main CVODE memory block.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

user_data (void *) pointer to the user data.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes If specified, the pointer to user_data is passed to all user-supplied functions that have

it as an argument. Otherwise, a NULL pointer is passed.

⚠

If user_data is needed in user linear solver or preconditioner functions, the call to CVodeSetUserData must be made *before* the call to specify the linear solver.

CVodeSetMaxOrd

Call flag = CVodeSetMaxOrder(cvode_mem, maxord);

Description The function CVodeSetMaxOrder specifies the maximum order of the linear multistep

method.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

maxord (int) value of the maximum method order. This must be positive.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CV_ILL_INPUT The specified value maxord is ≤ 0 , or larger than its previous value.

Notes The default value is ADAMS_Q_MAX = 12 for the Adams-Moulton method and BDF_Q_MAX

= 5 for the BDF method. Since maxord affects the memory requirements for the internal CVODE memory block, its value cannot be increased past its previous value.

An input value greater than the default will result in the default value.

CVodeSetMaxNumSteps

Call flag = CVodeSetMaxNumSteps(cvode_mem, mxsteps);

Description The function CVodeSetMaxNumSteps specifies the maximum number of steps to be taken

by the solver in its attempt to reach the next output time.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

mxsteps (long int) maximum allowed number of steps.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes Passing mxsteps = 0 results in CVODE using the default value (500).

Passing mxsteps < 0 disables the test (not recommended).

CVodeSetMaxHnilWarns

Call flag = CVodeSetMaxHnilWarns(cvode_mem, mxhnil);

Description The function CVodeSetMaxHnilWarns specifies the maximum number of messages issued

by the solver warning that t + h = t on the next internal step.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

mxhnil (int) maximum number of warning messages (>0).

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes The default value is 10. A negative value for mxhnil indicates that no warning messages

should be issued.

CVodeSetStabLimDet

Call flag = CVodeSetstabLimDet(cvode_mem, stldet);

Description The function CVodeSetStabLimDet indicates if the BDF stability limit detection algo-

rithm should be used. See §2.3 for further details.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

 $\begin{array}{ll} \mathtt{stldet} & (\mathtt{booleantype}) \ \mathrm{flag} \ \mathrm{controlling} \ \mathrm{stability} \ \mathrm{limit} \ \mathrm{detection} \ (\mathtt{SUNTRUE} = \mathrm{on}; \\ \mathtt{SUNFALSE} = \mathrm{off}). \end{array}$

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CV_ILL_INPUT The linear multistep method is not set to CV_BDF.

Notes The default value is SUNFALSE. If stldet = SUNTRUE when BDF is used and the method

order is greater than or equal to 3, then an internal function, CVsldet, is called to detect a possible stability limit. If such a limit is detected, then the order is reduced.

CVodeSetInitStep

Call flag = CVodeSetInitStep(cvode_mem, hin);

Description The function CVodeSetInitStep specifies the initial step size.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

hin (realtype) value of the initial step size to be attempted. Pass 0.0 to use

the default value.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes By default, CVODE estimates the initial step size to be the solution h of the equation

 $||0.5h^2\ddot{y}||_{\text{WRMS}} = 1$, where \ddot{y} is an estimated second derivative of the solution at t0.

CVodeSetMinStep

Call flag = CVodeSetMinStep(cvode_mem, hmin);

Description The function CVodeSetMinStep specifies a lower bound on the magnitude of the step

size.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

hmin (realtype) minimum absolute value of the step size (≥ 0.0).

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CV_ILL_INPUT Either hmin is nonpositive or it exceeds the maximum allowable step size.

Notes The default value is 0.0.

CVodeSetMaxStep

Call flag = CVodeSetMaxStep(cvode_mem, hmax);

Description The function CVodeSetMaxStep specifies an upper bound on the magnitude of the step

size.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

hmax (realtype) maximum absolute value of the step size (≥ 0.0).

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CV_ILL_INPUT Either hmax is nonpositive or it is smaller than the minimum allowable step size.

Notes Pass hmax = 0.0 to obtain the default value ∞ .

${\tt CVodeSetStopTime}$

Call flag = CVodeSetStopTime(cvode_mem, tstop);

Description The function CVodeSetStopTime specifies the value of the independent variable t past which the solution is not to proceed.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

tstop (realtype) value of the independent variable past which the solution should not proceed.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CV_ILL_INPUT The value of tstop is not beyond the current t value, t_n .

Notes The default, if this routine is not called, is that no stop time is imposed.

CVodeSetMaxErrTestFails

Call flag = CVodeSetMaxErrTestFails(cvode_mem, maxnef);

Description The function CVodeSetMaxErrTestFails specifies the maximum number of error test failures permitted in attempting one step.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

maxnef (int) maximum number of error test failures allowed on one step (>0).

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes The default value is 7.

CVodeSetMaxNonlinIters

Call flag = CVodeSetMaxNonlinIters(cvode_mem, maxcor);

Description The function CVodeSetMaxNonlinIters specifies the maximum number of nonlinear solver iterations permitted per step.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

maxcor (int) maximum number of nonlinear solver iterations allowed per step (>0).

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer or the SUNNONLINSOL module is NULL.

Notes The default value is 3.

CVodeSetMaxConvFails

Call flag = CVodeSetMaxConvFails(cvode_mem, maxncf);

Description The function CVodeSetMaxConvFails specifies the maximum number of nonlinear solver

convergence failures permitted during one step.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

maxncf (int) maximum number of allowable nonlinear solver convergence failures

per step (>0).

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes The default value is 10.

CVodeSetNonlinConvCoef

Call flag = CVodeSetNonlinConvCoef(cvode_mem, nlscoef);

Description The function CVodeSetNonlinConvCoef specifies the safety factor used in the nonlinear

convergence test (see $\S 2.1$).

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nlscoef (realtype) coefficient in nonlinear convergence test (> 0.0).

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes The default value is 0.1.

4.5.7.2 Direct linear solver interface optional input functions

The CVDLs solver interface needs a function to compute an approximation to the Jacobian matrix J(t,y). This function must be of type CVDlsJacFn. The user can supply a Jacobian function, or if using a dense or banded matrix J can use the default internal difference quotient approximation that comes with the CVDLs solver. To specify a user-supplied Jacobian function jac, CVDLs provides the function CVDlsSetJacFn. The CVDLs interface passes the pointer user_data to the Jacobian function. This allows the user to create an arbitrary structure with relevant problem data and access it during the execution of the user-supplied Jacobian function, without using global data in the program. The pointer user_data may be specified through CVodeSetUserData.

CVDlsSetJacFn

Call flag = CVDlsSetJacFn(cvode_mem, jac);

Description The function CVDlsSetJacFn specifies the Jacobian approximation function to be used.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

jac (CVDlsJacFn) user-defined Jacobian approximation function.

Return value The return value flag (of type int) is one of

CVDLS_SUCCESS The optional value has been successfully set.

CVDLS_MEM_NULL The cvode_mem pointer is NULL.

CVDLS_LMEM_NULL The CVDLS linear solver interface has not been initialized.

Notes By default, CVDLS uses an internal difference quotient function for dense and band matrices. If NULL is passed to jac, this default function is used. An error will occur if

no jac is supplied when using a sparse matrix.

The function type CVDlsJacFn is described in §4.6.5.

4.5.7.3 Iterative linear solver interface optional input functions

If preconditioning is utilized with the CVSPILS linear solver interface, then the user must supply a preconditioner solve function psolve and specify its name in a call to CVSpilsSetPreconditioner. The evaluation and preprocessing of any Jacobian-related data needed by the user's preconditioner solve function is done in the optional user-supplied function psetup. Both of these functions are fully specified in §4.6. If used, the psetup function should also be specified in the call to CVSpilsSetPreconditioner.

The pointer user_data received through CVodeSetUserData (or a pointer to NULL if user_data was not specified) is passed to the preconditioner psetup and psolve functions. This allows the user to create an arbitrary structure with relevant problem data and access it during the execution of the user-supplied preconditioner functions without using global data in the program.

The CVSPILS solver interface requires a function to compute an approximation to the product between the Jacobian matrix J(t,y) and a vector v. The user can supply a Jacobian-times-vector approximation function or use the default internal difference quotient function that comes with the CVSPILS interface. A user-defined Jacobian-vector function must be of type CVSpilsJacTimesVecFn and can be specified through a call to CVSpilsSetJacTimes (see §4.6.6 for specification details). As with the user-supplied preconditioner functions, the evaluation and processing of any Jacobian-related data needed by the user's Jacobian-times-vector function is done in the optional user-supplied function jtsetup (see §4.6.7 for specification details). As with the preconditioner functions, a pointer to the user-defined data structure, user_data, specified through CVodeSetUserData (or a NULL pointer otherwise) is passed to the Jacobian-times-vector setup and product functions, jtsetup and jtimes, each time they are called.

Finally, as described in Section 2.1, the CVSPILS interface requires that iterative linear solvers stop when the norm of the preconditioned residual is less than $0.05 \cdot (0.1\epsilon)$, where ϵ is the nonlinear solver tolerance. The user may adjust this linear solver tolerance by calling the function CVSpilsSetEpsLin.

CVSpilsSetPreconditioner

Call flag = CVSpilsSetPreconditioner(cvode_mem, psetup, psolve);

 $\label{preconditioner} Description \quad The \ function \ {\tt CVSpilsSetPreconditioner} \ specifies \ the \ preconditioner \ setup \ and \ solve$

functions.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

psetup (CVSpilsPrecSetupFn) user-defined preconditioner setup function. Pass

NULL if no setup is necessary.

psolve (CVSpilsPrecSolveFn) user-defined preconditioner solve function.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional values have been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

CVSPILS_SUNLS_FAIL An error occurred when setting up preconditioning in the SUN-LINSOL object used by the CVSPILS interface.

LINSOL object used by the CVSPILS interface

The function type CVSpilsPrecSolveFn is described in §4.6.8. The function type CVSpilsPrecSetupFn is described in §4.6.9.

CVSpilsSetJacTimes

Notes

Call flag = CVSpilsSetJacTimes(cvode_mem, jtsetup, jtimes);

Description The function CVSpilsSetJacTimes specifies the Jacobian-vector setup and product

functions.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

 $\verb|jtsetup| (\texttt{CVSpilsJacTimesSetupFn}) user-defined Jacobian-vector setup function. Pass$

NULL if no setup is necessary.

jtimes (CVSpilsJacTimesVecFn) user-defined Jacobian-vector product function.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

CVSPILS_SUNLS_FAIL An error occurred when setting up the system matrix-times-vector routines in the SUNLINSOL object used by the CVSPILS interface.

Notes By default, the CVSPILS linear solvers use an internal difference quotient function. If

NULL is passed to jtimes, this default function is used.

The function type CVSpilsJacTimesSetupFn is described in §4.6.7. The function type CVSpilsJacTimesVecFn is described in §4.6.6.

CVSpilsSetEpsLin

Call flag = CVSpilsSetEpsLin(cvode_mem, eplifac);

Description The function CVSpilsSetEpsLin specifies the factor by which the Krylov linear solver's

convergence test constant is reduced from the nonlinear solver test constant.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

eplifac (realtype) linear convergence safety factor (≥ 0.0).

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

CVSPILS_ILL_INPUT The factor eplifac is negative.

Notes The default value is 0.05.

If eplifac= 0.0 is passed, the default value is used.

4.5.7.4 Rootfinding optional input functions

The following functions can be called to set optional inputs to control the rootfinding algorithm.

CVodeSetRootDirection

Call flag = CVodeSetRootDirection(cvode_mem, rootdir);

Description The function CVodeSetRootDirection specifies the direction of zero-crossings to be

located and returned.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

rootdir (int *) state array of length nrtfn, the number of root functions g_i , as specified in the call to the function CVodeRootInit. A value of 0 for rootdir[i] indicates that crossing in either direction for g_i should be reported. A value of +1 or -1 indicates that the solver should report only zero-crossings where

 g_i is increasing or decreasing, respectively.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CV_ILL_INPUT rootfinding has not been activated through a call to CVodeRootInit.

Notes The default behavior is to monitor for both zero-crossing directions.

CVodeSetNoInactiveRootWarn

Call flag = CVodeSetNoInactiveRootWarn(cvode_mem);

Description The function CVodeSetNoInactiveRootWarn disables issuing a warning if some root

function appears to be identically zero at the beginning of the integration.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes CVODE will not report the initial conditions as a possible zero-crossing (assuming that

one or more components g_i are zero at the initial time). However, if it appears that some g_i is identically zero at the initial time (i.e., g_i is zero at the initial time and after the first step), CVODE will issue a warning which can be disabled with this optional

input function.

4.5.8 Interpolated output function

An optional function CVodeGetDky is available to obtain additional output values. This function should only be called after a successful return from CVode as it provides interpolated values either of y or of its derivatives (up to the current order of the integration method) interpolated to any value of t in the last internal step taken by CVODE.

The call to the CVodeGetDky function has the following form:

CVodeGetDky

Notes

Call flag = CVodeGetDky(cvode_mem, t, k, dky);

Description The function CVodeGet

The function CVodeGetDky computes the k-th derivative of the function y at time t, i.e. $d^{(k)}y/dt^{(k)}(t)$, where $t_n - h_u \le t \le t_n$, t_n denotes the current internal time reached, and h_u is the last internal step size successfully used by the solver. The user may request k $t_n - t_n = 0$, the garagest endow (entirely output along)

 $=0,1,\ldots,q_u$, where q_u is the current order (optional output qlast).

Arguments cvode_mem (void *) pointer to the CVODE memory block.

t (realtype) the value of the independent variable at which the derivative is

to be evaluated.

k (int) the derivative order requested.

dky (N_Vector) vector containing the derivative. This vector must be allocated

by the user.

Return value The return value flag (of type int) is one of

CV_SUCCESS CVodeGetDky succeeded.

 ${\tt CV_BAD_K} \qquad {\tt k} \ {\rm is \ not \ in \ the \ range} \ 0,1,\ldots,q_u.$

CV_BAD_T t is not in the interval $[t_n - h_u, t_n]$. CV_BAD_DKY The dky argument was NULL.

CV_MEM_NULL The cvode_mem argument was NULL.

CVINDILINOLL THE CVOGELHEIR argument was NOLL

It is only legal to call the function CVodeGetDky after a successful return from CVode. See CVodeGetCurrentTime, CVodeGetLastOrder, and CVodeGetLastStep in the next

section for access to t_n , q_u , and h_u , respectively.

4.5.9 Optional output functions

CVODE provides an extensive set of functions that can be used to obtain solver performance information. Table 4.3 lists all optional output functions in CVODE, which are then described in detail in the remainder of this section.

Some of the optional outputs, especially the various counters, can be very useful in determining how successful the CVODE solver is in doing its job. For example, the counters nsteps and nfevals provide a rough measure of the overall cost of a given run, and can be compared among runs with differing input options to suggest which set of options is most efficient. The ratio nniters/nsteps measures the performance of the nonlinear solver in solving the nonlinear systems at each time step; typical values for this range from 1.1 to 1.8. The ratio njevals/nniters (in the case of a direct linear solver), and the ratio npevals/nniters (in the case of an iterative linear solver) measure the overall degree of nonlinearity in these systems, and also the quality of the approximate Jacobian or preconditioner being used. Thus, for example, njevals/nniters can indicate if a user-supplied Jacobian is inaccurate, if this ratio is larger than for the case of the corresponding internal Jacobian. The ratio nliters/nniters measures the performance of the Krylov iterative linear solver, and thus (indirectly) the quality of the preconditioner.

4.5.9.1 SUNDIALS version information

The following functions provide a way to get SUNDIALS version information at runtime.

SUNDIALSGetVersion

Call flag = SUNDIALSGetVersion(version, len);

Description The function SUNDIALSGetVersion fills a character array with SUNDIALS version infor-

mation.

Arguments version (char *) character array to hold the SUNDIALS version information.

len (int) allocated length of the version character array.

Return value If successful, SUNDIALSGetVersion returns 0 and version contains the SUNDIALS ver-

sion information. Otherwise, it returns -1 and version is not set (the input character

array is too short).

Notes A string of 25 characters should be sufficient to hold the version information. Any

trailing characters in the version array are removed.

SUNDIALSGetVersionNumber

Call flag = SUNDIALSGetVersionNumber(&major, &minor, &patch, label, len);

 $Description \quad The \ function \ {\tt SUNDIALSGetVersionNumber} \ set \ integers \ for \ the \ {\tt SUNDIALS} \ major, \ minor,$

and patch release numbers and fills a character array with the release label if applicable.

Arguments major (int) SUNDIALS release major version number.

minor (int) SUNDIALS release minor version number.

patch (int) SUNDIALS release patch version number.

label (char *) character array to hold the SUNDIALS release label.

len (int) allocated length of the label character array.

Return value If successful, SUNDIALSGetVersionNumber returns 0 and the major, minor, patch, and

label values are set. Otherwise, it returns -1 and the values are not set (the input

character array is too short).

Notes A string of 10 characters should be sufficient to hold the label information. If a label

is not used in the release version, no information is copied to label. Any trailing

characters in the label array are removed.

Table 4.3: Optional outputs from CVODE, CVDLS, CVDIAG, and CVSPILS

Optional output	Function name					
CVODE main solv	ver					
Size of CVODE real and integer workspaces	CVodeGetWorkSpace					
Cumulative number of internal steps	CVodeGetNumSteps					
No. of calls to r.h.s. function	CVodeGetNumRhsEvals					
No. of calls to linear solver setup function	CVodeGetNumLinSolvSetups					
No. of local error test failures that have occurred	CVodeGetNumErrTestFails					
Order used during the last step	CVodeGetLastOrder					
Order to be attempted on the next step	CVodeGetCurrentOrder					
No. of order reductions due to stability limit detection	CVodeGetNumStabLimOrderReds					
Actual initial step size used	CVodeGetActualInitStep					
Step size used for the last step	CVodeGetLastStep					
Step size to be attempted on the next step	CVodeGetCurrentStep					
Current internal time reached by the solver	CVodeGetCurrentTime					
Suggested factor for tolerance scaling	CVodeGetTolScaleFactor					
Error weight vector for state variables	CVodeGetErrWeights					
Estimated local error vector	CVodeGetEstLocalErrors					
No. of nonlinear solver iterations	CVodeGetNumNonlinSolvIters					
No. of nonlinear convergence failures	CVodeGetNumNonlinSolvConvFails					
All CVODE integrator statistics	CVodeGetIntegratorStats					
CVODE nonlinear solver statistics	CVodeGetNonlinSolvStats					
Array showing roots found	CvodeGetRootInfo					
No. of calls to user root function	CVodeGetNumGEvals					
Name of constant associated with a return flag	CVodeGetReturnFlagName					
CVDLS linear solver interface						
Size of real and integer workspaces	CVDlsGetWorkSpace					
No. of Jacobian evaluations	CVDlsGetNumJacEvals					
No. of r.h.s. calls for finite diff. Jacobian evals.	CVDlsGetNumRhsEvals					
Last return from a linear solver function	CVDlsGetLastFlag					
Name of constant associated with a return flag	CVDlsGetReturnFlagName					
CVDIAG linear solver interface						
Size of CVDIAG real and integer workspaces	CVDiagGetWorkSpace					
No. of r.h.s. calls for finite diff. Jacobian evals.	CVDiagGetNumRhsEvals					
Last return from a CVDIAG function	CVDiagGetLastFlag					
Name of constant associated with a return flag	CVDiagGetReturnFlagName					
CVSPILS linear solver interface						
Size of real and integer workspaces	CVSpilsGetWorkSpace					
No. of linear iterations	${\tt CVSpilsGetNumLinIters}$					
No. of linear convergence failures	${\tt CVSpilsGetNumConvFails}$					
No. of preconditioner evaluations	CVSpilsGetNumPrecEvals					
No. of preconditioner solves	CVSpilsGetNumPrecSolves					
No. of Jacobian-vector setup evaluations	CVSpilsGetNumJTSetupEvals					
No. of Jacobian-vector product evaluations	CVSpilsGetNumJtimesEvals					
No. of r.h.s. calls for finite diff. Jacobian-vector evals.	CVSpilsGetNumRhsEvals					
Last return from a linear solver function	CVSpilsGetLastFlag					
Name of constant associated with a return flag	${\tt CVSpilsGetReturnFlagName}$					

4.5.9.2 Main solver optional output functions

CVODE provides several user-callable functions that can be used to obtain different quantities that may be of interest to the user, such as solver workspace requirements, solver performance statistics, as well as additional data from the CVODE memory block (a suggested tolerance scaling factor, the error weight vector, and the vector of estimated local errors). Functions are also provided to extract statistics related to the performance of the CVODE nonlinear solver used. As a convenience, additional information extraction functions provide the optional outputs in groups. These optional output functions are described next.

CVodeGetWorkSpace

Call flag = CVodeGetWorkSpace(cvode_mem, &lenrw, &leniw);

Description The function CVodeGetWorkSpace returns the CVODE real and integer workspace sizes.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

lenrw (long int) the number of realtype values in the CVODE workspace.

leniw (long int) the number of integer values in the CVODE workspace.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output values have been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes

In terms of the problem size N, the maximum method order maxord, and the number nrtfn of root functions (see §4.5.5), the actual size of the real workspace, in realtype words, is given by the following:

- base value: lenrw = $96 + (maxord+5) * N_r + 3*nrtfn$;
- using CVodeSVtolerances: lenrw = lenrw $+N_r$;

where N_r is the number of real words in one N_Vector ($\approx N$).

The size of the integer workspace (without distinction between int and long int words) is given by:

- base value: leniw = $40 + (maxord+5) * N_i + nrtfn;$
- using CVodeSVtolerances: leniw = leniw $+N_i$;

where N_i is the number of integer words in one N_Vector (= 1 for NVECTOR_SERIAL and 2*npes for NVECTOR_PARALLEL and npes processors).

For the default value of maxord, no rootfinding, and without using CVodeSVtolerances, these lengths are given roughly by:

- For the Adams method: lenrw = 96 + 17N and leniw = 57
- For the BDF method: lenrw = 96 + 10N and leniw = 50

CVodeGetNumSteps

Call flag = CVodeGetNumSteps(cvode_mem, &nsteps);

Description The function CVodeGetNumSteps returns the cumulative number of internal steps taken by the solver (total so far).

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nsteps (long int) number of steps taken by CVODE.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CVodeGetNumRhsEvals

Call flag = CVodeGetNumRhsEvals(cvode_mem, &nfevals);

Description The function CVodeGetNumRhsEvals returns the number of calls to the user's right-hand

side function.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nfevals (long int) number of calls to the user's f function.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes The nfevals value returned by CVodeGetNumRhsEvals does not account for calls made

to f by a linear solver or preconditioner module.

CVodeGetNumLinSolvSetups

Call flag = CVodeGetNumLinSolvSetups(cvode_mem, &nlinsetups);

Description The function CVodeGetNumLinSolvSetups returns the number of calls made to the

linear solver's setup function.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nlinsetups (long int) number of calls made to the linear solver setup function.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CVodeGetNumErrTestFails

Call flag = CVodeGetNumErrTestFails(cvode_mem, &netfails);

Description The function CVodeGetNumErrTestFails returns the number of local error test failures

that have occurred.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

netfails (long int) number of error test failures.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CVodeGetLastOrder

Call flag = CVodeGetLastOrder(cvode_mem, &qlast);

Description The function CVodeGetLastOrder returns the integration method order used during the

last internal step.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

qlast (int) method order used on the last internal step.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CVodeGetCurrentOrder

Call flag = CVodeGetCurrentOrder(cvode_mem, &qcur);

Description The function CVodeGetCurrentOrder returns the integration method order to be used

on the next internal step.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

qcur (int) method order to be used on the next internal step.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CVodeGetLastStep

Call flag = CVodeGetLastStep(cvode_mem, &hlast);

Description The function CVodeGetLastStep returns the integration step size taken on the last

internal step.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

hlast (realtype) step size taken on the last internal step.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

${\tt CVodeGetCurrentStep}$

Call flag = CVodeGetCurrentStep(cvode_mem, &hcur);

Description The function CVodeGetCurrentStep returns the integration step size to be attempted

on the next internal step.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

hcur (realtype) step size to be attempted on the next internal step.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CVodeGetActualInitStep

Call flag = CVodeGetActualInitStep(cvode_mem, &hinused);

Description The function CVodeGetActualInitStep returns the value of the integration step size

used on the first step.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

hinused (realtype) actual value of initial step size.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes Even if the value of the initial integration step size was specified by the user through

a call to CVodeSetInitStep, this value might have been changed by CVODE to ensure that the step size is within the prescribed bounds $(h_{\min} \leq h_0 \leq h_{\max})$, or to satisfy the

local error test condition.

CVodeGetCurrentTime

Call flag = CVodeGetCurrentTime(cvode_mem, &tcur);

Description The function CVodeGetCurrentTime returns the current internal time reached by the

solver.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

tcur (realtype) current internal time reached.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CVodeGetNumStabLimOrderReds

Call flag = CVodeGetNumStabLimOrderReds(cvode_mem, &nslred);

Description The function CVodeGetNumStabLimOrderReds returns the number of order reductions

dictated by the BDF stability limit detection algorithm (see §2.3).

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nslred (long int) number of order reductions due to stability limit detection.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes If the stability limit detection algorithm was not initialized (CVodeSetStabLimDet was

not called), then nslred = 0.

CVodeGetTolScaleFactor

Call flag = CVodeGetTolScaleFactor(cvode_mem, &tolsfac);

 $\label{prop:condition} \textbf{Description} \quad \text{The function $\tt CVodeGetTolScaleFactor returns a suggested factor by which the user's}$

tolerances should be scaled when too much accuracy has been requested for some internal α

step.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

tolsfac (realtype) suggested scaling factor for user-supplied tolerances.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CVodeGetErrWeights

Call flag = CVodeGetErrWeights(cvode_mem, eweight);

Description The function CVodeGetErrWeights returns the solution error weights at the current

time. These are the reciprocals of the W_i given by (2.7).

Arguments cvode_mem (void *) pointer to the CVODE memory block.

eweight (N_Vector) solution error weights at the current time.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

 ${\tt CV_MEM_NULL}$ The ${\tt cvode_mem}$ pointer is NULL.

Notes The user must allocate memory for eweight.

CVodeGetEstLocalErrors

Call flag = CVodeGetEstLocalErrors(cvode_mem, ele);

Description The function CVodeGetEstLocalErrors returns the vector of estimated local errors.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

ele (N_Vector) estimated local errors.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

⚠

Notes The user must allocate memory for ele.

The values returned in ele are valid only if CVode returned a non-negative value.

The ele vector, together with the eweight vector from CVodeGetErrWeights, can be used to determine how the various components of the system contributed to the estimated local error test. Specifically, that error test uses the RMS norm of a vector whose components are the products of the components of these two vectors. Thus, for example, if there were recent error test failures, the components causing the failures are those with largest values for the products, denoted loosely as eweight[i]*ele[i].

CVodeGetIntegratorStats

Call flag = CVodeGetIntegratorStats(cvode_mem, &nsteps, &nfevals,

&nlinsetups, &netfails, &qlast, &qcur, &hinused, &hlast, &hcur, &tcur);

 $\label{thm:condegetIntegratorStats} Description \quad The \ function \ {\tt CVodeGetIntegratorStats} \ returns \ the \ {\tt CVode} \ integrator \ statistics \ as \ a$

group.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nsteps (long int) number of steps taken by CVODE.

nfevals (long int) number of calls to the user's f function.

nlinsetups (long int) number of calls made to the linear solver setup function.

netfails (long int) number of error test failures.

glast (int) method order used on the last internal step.

gcur (int) method order to be used on the next internal step.

hinused (realtype) actual value of initial step size.

hlast (realtype) step size taken on the last internal step.

hcur (realtype) step size to be attempted on the next internal step.

tcur (realtype) current internal time reached.

Return value The return value flag (of type int) is one of

CV_SUCCESS the optional output values have been successfully set.

CV_MEM_NULL the cvode_mem pointer is NULL.

CVodeGetNumNonlinSolvIters

Call flag = CVodeGetNumNonlinSolvIters(cvode_mem, &nniters);

Description The function CVodeGetNumNonlinSolvIters returns the number of nonlinear iterations

performed.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nniters (long int) number of nonlinear iterations performed.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output values have been successfully set.

CV_MEM_NULL The cvode_mem pointer or the SUNNONLINSOL module is NULL.

${\tt CVodeGetNumNonlinSolvConvFails}$

Call flag = CVodeGetNumNonlinSolvConvFails(cvode_mem, &nncfails);

Description The function CVodeGetNumNonlinSolvConvFails returns the number of nonlinear con-

vergence failures that have occurred.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nncfails (long int) number of nonlinear convergence failures.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

CVodeGetNonlinSolvStats

Call flag = CVodeGetNonlinSolvStats(cvode_mem, &nniters, &nncfails);

Description The function CVodeGetNonlinSolvStats returns the CVODE nonlinear solver statistics

as a group.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nniters (long int) number of nonlinear iterations performed.
nncfails (long int) number of nonlinear convergence failures.

Return value The return value flag (of type int) is one of

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer or the SUNNONLINSOL module is NULL.

${\tt CVodeGetReturnFlagName}$

Description The function CVodeGetReturnFlagName returns the name of the CVODE constant cor-

responding to flag.

Arguments The only argument, of type int, is a return flag from a CVODE function.

Return value The return value is a string containing the name of the corresponding constant.

4.5.9.3 Rootfinding optional output functions

There are two optional output functions associated with rootfinding.

CVodeGetRootInfo

Call flag = CVodeGetRootInfo(cvode_mem, rootsfound);

Description The function CVodeGetRootInfo returns an array showing which functions were found

to have a root.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

rootsfound (int *) array of length nrtfn with the indices of the user functions g_i found to have a root. For $i=0,\ldots,$ nrtfn-1, rootsfound $[i]\neq 0$ if g_i has a

root, and = 0 if not.

Return value The return value flag (of type int) is one of:

CV_SUCCESS The optional output values have been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

Notes Note that, for the components g_i for which a root was found, the sign of rootsfound[i]

indicates the direction of zero-crossing. A value of +1 indicates that g_i is increasing,

while a value of -1 indicates a decreasing g_i .

The user must allocate memory for the vector rootsfound.

CVodeGetNumGEvals

Call flag = CVodeGetNumGEvals(cvode_mem, &ngevals);

Description The function CVodeGetNumGEvals returns the cumulative number of calls made to the

user-supplied root function g.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

ngevals (long int) number of calls made to the user's function g thus far.

Return value The return value flag (of type int) is one of:

CV_SUCCESS The optional output value has been successfully set.

CV_MEM_NULL The cvode_mem pointer is NULL.

4.5.9.4 Direct linear solver interface optional output functions

The following optional outputs are available from the CVDLS modules: workspace requirements, number of calls to the Jacobian routine, number of calls to the right-hand side routine for finite-difference Jacobian approximation, and last return value from a CVDLS function. Note that, where the name of an output would otherwise conflict with the name of an optional output from the main solver, a suffix LS (for Linear Solver) has been added (e.g. lenrwLS).

CVDlsGetWorkSpace

Call flag = CVDlsGetWorkSpace(cvode_mem, &lenrwLS, &leniwLS);

Description The function CVDlsGetWorkSpace returns the sizes of the real and integer workspaces

used by the CVDLS linear solver interface.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

LenrwLS (long int) the number of realtype values in the CVDLS workspace.

leniwLS (long int) the number of integer values in the CVDLS workspace.

Return value The return value flag (of type int) is one of

CVDLS_SUCCESS The optional output values have been successfully set.

 ${\tt CVDLS_MEM_NULL} \quad {\tt The} \ {\tt cvode_mem} \ {\tt pointer} \ {\tt is} \ {\tt NULL}.$

CVDLS_LMEM_NULL The CVDLS linear solver has not been initialized.

Notes The workspace requirements reported by this routine correspond only to memory allo-

cated within this interface and to memory allocated by the SUNLINSOL object attached to it. The template Jacobian matrix allocated by the user outside of CVDLS is not

included in this report.

CVDlsGetNumJacEvals

Call flag = CVDlsGetNumJacEvals(cvode_mem, &njevals);

Description The function CVDlsGetNumJacEvals returns the number of calls made to the CVDLS

Jacobian approximation function.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

njevals (long int) the number of calls to the Jacobian function.

Return value The return value flag (of type int) is one of

CVDLS_SUCCESS The optional output value has been successfully set.

CVDLS_MEM_NULL The cvode_mem pointer is NULL.

CVDLS_LMEM_NULL The CVDLS linear solver has not been initialized.

CVDlsGetNumRhsEvals

Call flag = CVDlsGetNumRhsEvals(cvode_mem, &nfevalsLS);

Description The function CVDlsGetNumRhsEvals returns the number of calls made to the user-

supplied right-hand side function due to the finite difference Jacobian approximation.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nfevalsLS (long int) the number of calls made to the user-supplied right-hand side

function.

Return value The return value flag (of type int) is one of

CVDLS_SUCCESS The optional output value has been successfully set.

CVDLS_MEM_NULL The cvode_mem pointer is NULL.

CVDLS_LMEM_NULL The CVDLS linear solver has not been initialized.

Notes The value nfevalsLS is incremented only if one of the default internal difference quotient

functions (dense or banded) is used.

CVDlsGetLastFlag

Call flag = CVDlsGetLastFlag(cvode_mem, &lsflag);

Description The function CVDlsGetLastFlag returns the last return value from a CVDLs routine.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

lsflag (long int) the value of the last return flag from a CVDLS function.

Return value The return value flag (of type int) is one of

CVDLS_SUCCESS The optional output value has been successfully set.

CVDLS_MEM_NULL The cvode_mem pointer is NULL.

CVDLS_LMEM_NULL The CVDLS linear solver has not been initialized.

Notes If the SUNLINSOL_DENSE or SUNLINSOL_BAND setup function failed (CVode returned

 ${\tt CV_LSETUP_FAIL}), \ {\tt then} \ {\tt the} \ {\tt value} \ {\tt of} \ {\tt lsflag} \ {\tt is} \ {\tt equal} \ {\tt to} \ {\tt the} \ {\tt column} \ {\tt index} \ ({\tt numbered} \ {\tt from} \ {\tt one}) \ {\tt at} \ {\tt which} \ {\tt a} \ {\tt zero} \ {\tt diagonal} \ {\tt element} \ {\tt was} \ {\tt encountered} \ {\tt during} \ {\tt the} \ {\tt LU} \ {\tt factorization}$

of the (dense or banded) Jacobian matrix.

CVDlsGetReturnFlagName

Call name = CVDlsGetReturnFlagName(lsflag);

Description The function CVDlsGetReturnFlagName returns the name of the CVDLS constant corre-

sponding to lsflag.

Arguments The only argument, of type long int, is a return flag from a CVDLS function.

Return value The return value is a string containing the name of the corresponding constant.

If $1 \leq lsflag \leq N$ (LU factorization failed), this routine returns "NONE".

4.5.9.5 Iterative linear solver interface optional output functions

The following optional outputs are available from the CVSPILS modules: workspace requirements, number of linear iterations, number of linear convergence failures, number of calls to the preconditioner setup and solve routines, number of calls to the Jacobian-vector setup and product routines, number of calls to the right-hand side routine for finite-difference Jacobian-vector product approximation, and last return value from a linear solver function. Note that, where the name of an output would otherwise conflict with the name of an optional output from the main solver, a suffix LS (for Linear Solver) has been added (e.g. lenrwLS).

CVSpilsGetWorkSpace

Call flag = CVSpilsGetWorkSpace(cvode_mem, &lenrwLS, &leniwLS);

Description The function CVSpilsGetWorkSpace returns the global sizes of the CVSPILS real and

integer workspaces.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

lenrwLS (long int) the number of realtype values in the CVSPILS workspace.

leniwLS (long int) the number of integer values in the CVSPILS workspace.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

Notes

The workspace requirements reported by this routine correspond only to memory allocated within this interface and to memory allocated by the SUNLINSOL object attached to it

In a parallel setting, the above values are global (i.e., summed over all processors).

CVSpilsGetNumLinIters

Call flag = CVSpilsGetNumLinIters(cvode_mem, &nliters);

Description The function CVSpilsGetNumLinIters returns the cumulative number of linear itera-

tions.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nliters (long int) the current number of linear iterations.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

${\tt CVSpilsGetNumConvFails}$

Call flag = CVSpilsGetNumConvFails(cvode_mem, &nlcfails);

Description The function CVSpilsGetNumConvFails returns the cumulative number of linear con-

vergence failures.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nlcfails (long int) the current number of linear convergence failures.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

CVSpilsGetNumPrecEvals

Call flag = CVSpilsGetNumPrecEvals(cvode_mem, &npevals);

Description The function CVSpilsGetNumPrecEvals returns the number of preconditioner evalua-

tions, i.e., the number of calls made to psetup with jok = SUNFALSE.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

npevals (long int) the current number of calls to psetup.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

CVSpilsGetNumPrecSolves

Call flag = CVSpilsGetNumPrecSolves(cvode_mem, &npsolves);

Description The function CVSpilsGetNumPrecSolves returns the cumulative number of calls made

to the preconditioner solve function, psolve.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

npsolves (long int) the current number of calls to psolve.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

CVSpilsGetNumJTSetupEvals

Call flag = CVSpilsGetNumJTSetupEvals(cvode_mem, &njtsetup);

Description The function CVSpilsGetNumJTSetupEvals returns the cumulative number of calls

made to the Jacobian-vector setup function jtsetup.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

njtsetup (long int) the current number of calls to jtsetup.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

CVSpilsGetNumJtimesEvals

Call flag = CVSpilsGetNumJtimesEvals(cvode_mem, &njvevals);

Description The function CVSpilsGetNumJtimesEvals returns the cumulative number of calls made

to the Jacobian-vector function jtimes.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

njvevals (long int) the current number of calls to jtimes.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

CVSpilsGetNumRhsEvals

Call flag = CVSpilsGetNumRhsEvals(cvode_mem, &nfevalsLS);

Description The function CVSpilsGetNumRhsEvals returns the number of calls to the user right-

hand side function for finite difference Jacobian-vector product approximation.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nfevalsLS (long int) the number of calls to the user right-hand side function.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

Notes The value nfevalsLS is incremented only if the default CVSpilsDQJtimes difference

quotient function is used.

CVSpilsGetLastFlag

Call flag = CVSpilsGetLastFlag(cvode_mem, &lsflag);

Description The function CVSpilsGetLastFlag returns the last return value from a CVSPILS routine.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

1sflag (long int) the value of the last return flag from a CVSPILS function.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer is NULL.

CVSPILS_LMEM_NULL The CVSPILS linear solver has not been initialized.

Notes If the CVSPILS setup function failed (CVode returned CV_LSETUP_FAIL), lsflag will be SUNLS_PSET_FAIL_UNREC, SUNLS_ASET_FAIL_UNREC, or SUNLS_PACKAGE_FAIL_UNREC.

If the CVSPILS solve function failed (CVode returned CV_LSOLVE_FAIL), 1sflag contains the error return flag from the SUNLINSOL object, which will be one of: SUNLS_MEM_NULL, indicating that the SUNLINSOL memory is NULL; SUNLS_ATIMES_FAIL_UNREC, indicating an unrecoverable failure in the J*v function; SUNLS_PSOLVE_FAIL_UNREC, indicating that the preconditioner solve function psolve failed unrecoverably; SUNLS_GS_FAIL, indicating a failure in the Gram-Schmidt procedure (SPGMR and SPFGMR only); SUNLS_QRSOL_FAIL, indicating that the matrix R was found to be singular during the QR solve phase (SPGMR and SPFGMR only); or SUNLS_PACKAGE_FAIL_UNREC, indicating an unrecoverable failure in an external iterative linear solver package.

CVSpilsGetReturnFlagName

Description The function CVSpilsGetReturnFlagName returns the name of the CVSPILS constant

corresponding to lsflag.

Arguments The only argument, of type long int, is a return flag from a CVSPILS function.

Return value The return value is a string containing the name of the corresponding constant.

4.5.9.6 Diagonal linear solver interface optional output functions

The following optional outputs are available from the CVDIAG module: workspace requirements, number of calls to the right-hand side routine for finite-difference Jacobian approximation, and last return value from a CVDIAG function. Note that, where the name of an output would otherwise conflict with the name of an optional output from the main solver, a suffix LS (for Linear Solver) has been added here (e.g. lenrwLS).

CVDiagGetWorkSpace

Call flag = CVDiagGetWorkSpace(cvode_mem, &lenrwLS, &leniwLS);

Description The function CVDiagGetWorkSpace returns the CVDIAG real and integer workspace sizes.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

> lenrwLS (long int) the number of realtype values in the CVDIAG workspace. leniwLS (long int) the number of integer values in the CVDIAG workspace.

Return value The return value flag (of type int) is one of

CVDIAG_SUCCESS The optional output valus have been successfully set.

CVDIAG_MEM_NULL The cvode_mem pointer is NULL.

CVDIAG_LMEM_NULL The CVDIAG linear solver has not been initialized.

Notes In terms of the problem size N, the actual size of the real workspace is roughly 3N

realtype words.

${\tt CVDiagGetNumRhsEvals}$

Call flag = CVDiagGetNumRhsEvals(cvode_mem, &nfevalsLS);

Description The function CVDiagGetNumRhsEvals returns the number of calls made to the user-

supplied right-hand side function due to the finite difference Jacobian approximation.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nfevalsLS (long int) the number of calls made to the user-supplied right-hand side

function.

Return value The return value flag (of type int) is one of

CVDIAG_SUCCESS The optional output value has been successfully set.

CVDIAG_MEM_NULL The cvode_mem pointer is NULL.

CVDIAG_LMEM_NULL The CVDIAG linear solver has not been initialized.

Notes The number of diagonal approximate Jacobians formed is equal to the number of calls

made to the linear solver setup function (see CVodeGetNumLinSolvSetups).

CVDiagGetLastFlag

Call flag = CVDiagGetLastFlag(cvode_mem, &lsflag);

Description The function CVDiagGetLastFlag returns the last return value from a CVDIAG routine.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

> (long int) the value of the last return flag from a CVDIAG function. lsflag

Return value The return value flag (of type int) is one of

CVDIAG_SUCCESS The optional output value has been successfully set.

CVDIAG_MEM_NULL The cvode_mem pointer is NULL.

CVDIAG_LMEM_NULL The CVDIAG linear solver has not been initialized.

If the CVDIAG setup function failed (CVode returned CV_LSETUP_FAIL), the value of Notes lsflag is equal to CVDIAG_INV_FAIL, indicating that a diagonal element with value zero

was encountered. The same value is also returned if the CVDIAG solve function failed

(CVode returned CV_LSOLVE_FAIL).

CVDiagGetReturnFlagName

Call name = CVDiagGetReturnFlagName(lsflag);

Description The function CVDiagGetReturnFlagName returns the name of the CVDIAG constant

corresponding to lsflag.

Arguments The only argument, of type long int, is a return flag from a CVDIAG function.

Return value The return value is a string containing the name of the corresponding constant.

4.5.10 CVODE reinitialization function

The function CVodeReInit reinitializes the main CVODE solver for the solution of a new problem, where a prior call to CVodeInit been made. The new problem must have the same size as the previous one. CVodeReInit performs the same input checking and initializations that CVodeInit does, but does no memory allocation, as it assumes that the existing internal memory is sufficient for the new problem. A call to CVodeReInit deletes the solution history that was stored internally during the previous integration. Following a successful call to CVodeReInit, call CVode again for the solution of the new problem.

The use of CVodeReInit requires that the maximum method order, denoted by maxord, be no larger for the new problem than for the previous problem. This condition is automatically fulfilled if the multistep method parameter lmm is unchanged (or changed from CV_ADAMS to CV_BDF) and the default value for maxord is specified.

If there are changes to the linear solver specifications, make the appropriate calls to either the linear solver objects themselves, or to the CVDLS or CVSPILS interface routines, as described in §4.5.3. Otherwise, all solver inputs set previously remain in effect.

One important use of the CVodeReInit function is in the treating of jump discontinuities in the RHS function. Except in cases of fairly small jumps, it is usually more efficient to stop at each point of discontinuity and restart the integrator with a readjusted ODE model, using a call to CVodeReInit. To stop when the location of the discontinuity is known, simply make that location a value of tout. To stop when the location of the discontinuity is determined by the solution, use the rootfinding feature. In either case, it is critical that the RHS function not incorporate the discontinuity, but rather have a smooth extention over the discontinuity, so that the step across it (and subsequent rootfinding, if used) can be done efficiently. Then use a switch within the RHS function (communicated through user_data) that can be flipped between the stopping of the integration and the restart, so that the restarted problem uses the new values (which have jumped). Similar comments apply if there is to be a jump in the dependent variable vector.

CVodeReInit

Call flag = CVodeReInit(cvode_mem, t0, y0);

Description The function CVodeReInit provides required problem specifications and reinitializes

CVODE.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

t0 (realtype) is the initial value of t. y0 (N_Vector) is the initial value of y.

Return value The return value flag (of type int) will be one of the following:

CV_SUCCESS The call to CVodeReInit was successful.

CV_MEM_NULL The CVODE memory block was not initialized through a previous call to CVodeCreate.

CV_NO_MALLOC Memory space for the CVODE memory block was not allocated through a previous call to CVodeInit.

CV_ILL_INPUT An input argument to CVodeReInit has an illegal value.

Notes If an error occurred, CVodeReInit also sends an error message to the error handler function.

4.6 User-supplied functions

The user-supplied functions consist of one function defining the ODE, (optionally) a function that handles error and warning messages, (optionally) a function that provides the error weight vector, (optionally) one or two functions that provide Jacobian-related information for the linear solver, and (optionally) one or two functions that define the preconditioner for use in any of the Krylov iterative algorithms.

4.6.1 ODE right-hand side

The user must provide a function of type CVRhsFn defined as follows:

CVRhsFn

Definition typedef int (*CVRhsFn)(realtype t, N_Vector y, N_Vector ydot, void *user_data);

Purpose This function computes the ODE right-hand side for a given value of the independent

variable t and state vector y.

Arguments t is the current value of the independent variable.

y is the current value of the dependent variable vector, y(t).

ydot is the output vector f(t, y).

user_data is the user_data pointer passed to CVodeSetUserData.

Return value A CVRhsFn should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODE will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CV_RHSFUNC_FAIL is returned).

Notes Allocation of memory for ydot is handled within CVODE.

A recoverable failure error return from the CVRhsFn is typically used to flag a value of the dependent variable y that is "illegal" in some way (e.g., negative where only a nonnegative value is physically meaningful). If such a return is made, CVODE will attempt to recover (possibly repeating the nonlinear solve, or reducing the step size) in order to avoid this recoverable error return.

For efficiency reasons, the right-hand side function is not evaluated at the converged solution of the nonlinear solver. Therefore, in general, a recoverable error in that converged value cannot be corrected. (It may be detected when the right-hand side function is called the first time during the following integration step, but a successful step cannot be undone.)

There are two other situations in which recovery is not possible even if the right-hand side function returns a recoverable error flag. One is when this occurs at the very first call to the CVRhsFn (in which case CVODE returns CV_FIRST_RHSFUNC_ERR). The other is when a recoverable error is reported by CVRhsFn after an error test failure, while the linear multistep method order is equal to 1 (in which case CVODE returns CV_UNREC_RHSFUNC_ERR).

4.6.2 Error message handler function

As an alternative to the default behavior of directing error and warning messages to the file pointed to by errfp (see CVodeSetErrFile), the user may provide a function of type CVErrHandlerFn to process any such messages. The function type CVErrHandlerFn is defined as follows:

CVErrHandlerFn

Definition typedef void (*CVErrHandlerFn)(int error_code, const char *module, const char *function, char *msg, void *eh_data);

Purpose This function processes error and warning messages from CVODE and its sub-modules.

Arguments error_code is the error code.

module is the name of the CVODE module reporting the error.

function is the name of the function in which the error occurred.

msg is the error message.

eh_data is a pointer to user data, the same as the eh_data parameter passed to

CVodeSetErrHandlerFn.

Return value A CVErrHandlerFn function has no return value.

Notes error_code is negative for errors and positive (CV_WARNING) for warnings. If a function that returns a pointer to memory encounters an error, it sets error_code to 0.

4.6.3 Error weight function

As an alternative to providing the relative and absolute tolerances, the user may provide a function of type CVEwtFn to compute a vector ewt containing the weights in the WRMS norm $||v||_{WRMS} = \sqrt{(1/N)\sum_{1}^{N}(W_i \cdot v_i)^2}$. These weights will be used in place of those defined by Eq. (2.7). The function type CVEwtFn is defined as follows:

CVEwtFn

Definition typedef int (*CVEwtFn)(N_Vector y, N_Vector ewt, void *user_data);

Purpose This function computes the WRMS error weights for the vector y.

Arguments y is the value of the dependent variable vector at which the weight vector is

to be computed.

ewt is the output vector containing the error weights.

user_data is a pointer to user data, the same as the user_data parameter passed to CVodeSetUserData.

Return value A CVEwtFn function type must return 0 if it successfully set the error weights and -1 otherwise.

Notes Allocation of memory for ewt is handled within CVODE.

The error weight vector must have all components positive. It is the user's responsibility to perform this test and return -1 if it is not satisfied.

4.6.4 Rootfinding function

If a rootfinding problem is to be solved during the integration of the ODE system, the user must supply a C function of type CVRootFn, defined as follows:

CVRootFn

Definition typedef int (*CVRootFn)(realtype t, N_Vector y, realtype *gout, void *user_data);

Purpose This function implements a vector-valued function g(t,y) such that the roots of the

nrtfn components $g_i(t, y)$ are sought.

Arguments t is the current value of the independent variable.

y is the current value of the dependent variable vector, y(t).

gout is the output array, of length nrtfn, with components $g_i(t, y)$.

user_data is a pointer to user data, the same as the user_data parameter passed to CVodeSetUserData.

Return value A CVRootFn should return 0 if successful or a non-zero value if an error occurred (in which case the integration is halted and CVode returns CV_RTFUNC_FAIL).

Notes Allocation of memory for gout is automatically handled within CVODE.

4.6.5 Jacobian information (direct method Jacobian)

If the direct linear solver interface is used (i.e., CVDlsSetLinearSolver is called in the steps described in §4.4), the user may provide a function of type CVDlsJacFn defined as follows:

CVDlsJacFn

Notes

Definition typedef (*CVDlsJacFn)(realtype t, N_Vector y, N_Vector fy,

SUNMatrix Jac, void *user_data,

N_Vector tmp1, N_Vector tmp2, N_Vector tmp3);

Purpose This function computes the Jacobian matrix $J = \partial f/\partial y$ (or an approximation to it).

Arguments t is the current value of the independent variable.

y is the current value of the dependent variable vector, namely the predicted

value of y(t).

fy is the current value of the vector f(t, y).

Jac is the output Jacobian matrix (of type SUNMatrix).

user_data is a pointer to user data, the same as the user_data parameter passed to

CVodeSetUserData.

tmp1 tmp2

 ${\tt tmp3}$ are pointers to memory allocated for variables of type ${\tt N_Vector}$ which can

be used by a CVDlsJacFn function as temporary storage or work space.

Return value A CVDlsJacFn should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODE will attempt to correct, while CVDLS sets last_flag to CVDLS_JACFUNC_RECVR), or a negative value if it failed unrecoverably (in which case the integration is halted, CVode returns CV_LSETUP_FAIL and CVDLS sets last_flag to CVDLS_JACFUNC_UNRECVR).

Information regarding the structure of the specific SUNMATRIX structure (e.g. number of rows, upper/lower bandwidth, sparsity type) may be obtained through using the implementation-specific SUNMATRIX interface functions (see Chapter 7 for details).

Prior to calling the user-supplied Jacobian function, the Jacobian matrix J(t,y) is zeroed out, so only nonzero elements need to be loaded into Jac.

If the user's CVDlsJacFn function uses difference quotient approximations, then it may need to access quantities not in the argument list. These include the current step size, the error weights, etc. To obtain these, the user will need to add a pointer to cv_mem to user_data and then use the CVodeGet* functions described in §4.5.9.2. The unit roundoff can be accessed as UNIT_ROUNDOFF defined in sundials_types.h.

dense:

A user-supplied dense Jacobian function must load the N by N dense matrix Jac with an approximation to the Jacobian matrix J(t,y) at the point (t, y). The accessor macros SM_ELEMENT_D and SM_COLUMN_D allow the user to read and write dense matrix elements without making explicit references to the underlying representation of the SUN-MATRIX_DENSE type. SM_ELEMENT_D(J, i, j) references the (i, j)-th element of the

dense matrix Jac (with i, j = 0...N-1). This macro is meant for small problems for which efficiency of access is not a major concern. Thus, in terms of the indices m and n ranging from 1 to N, the Jacobian element $J_{m,n}$ can be set using the statement SM_ELEMENT_D(J, m-1, n-1) = $J_{m,n}$. Alternatively, SM_COLUMN_D(J, j) returns a pointer to the first element of the j-th column of Jac (with j = 0...N-1), and the elements of the j-th column can then be accessed using ordinary array indexing. Consequently, $J_{m,n}$ can be loaded using the statements col_n = SM_COLUMN_D(J, n-1); col_n[m-1] = $J_{m,n}$. For large problems, it is more efficient to use SM_COLUMN_D than to use SM_ELEMENT_D. Note that both of these macros number rows and columns starting from 0. The SUNMATRIX_DENSE type and accessor macros are documented in §7.1.

banded:

A user-supplied banded Jacobian function must load the N by N banded matrix Jac with the elements of the Jacobian J(t,y) at the point (t,y). The accessor macros SM_ELEMENT_B, SM_COLUMN_B, and SM_COLUMN_ELEMENT_B allow the user to read and write band matrix elements without making specific references to the underlying representation of the SUNMATRIX_BAND type. SM_ELEMENT_B(J, i, j) references the (i, j)-th element of the band matrix Jac, counting from 0. This macro is meant for use in small problems for which efficiency of access is not a major concern. Thus, in terms of the indices m and n ranging from 1 to N with (m,n) within the band defined by mupper and mlower, the Jacobian element $J_{m,n}$ can be loaded using the statement SM_ELEMENT_B(J, m-1, n-1) = $J_{m,n}$. The elements within the band are those with -mupper \leq m-n \leq mlower. Alternatively, SM_COLUMN_B(J, j) returns a pointer to the diagonal element of the j-th column of Jac, and if we assign this address to realtype *col_j, then the i-th element of the j-th column is given by SM_COLUMN_ELEMENT_B(col_j, i, j), counting from 0. Thus, for (m,n) within the band, $J_{m,n}$ can be loaded by setting col_n = SM_COLUMN_B(J, n-1); SM_COLUMN_ELEMENT_B(col_n, m-1, n-1) = $J_{m,n}$. The elements of the j-th column can also be accessed via ordinary array indexing, but this approach requires knowledge of the underlying storage for a band matrix of type SUN-MATRIX_BAND. The array col_n can be indexed from -mupper to mlower. For large problems, it is more efficient to use SM_COLUMN_B and SM_COLUMN_ELEMENT_B than to use the SM_ELEMENT_B macro. As in the dense case, these macros all number rows and columns starting from 0. The SUNMATRIX_BAND type and accessor macros are documented in $\S7.2$.

sparse:

A user-supplied sparse Jacobian function must load the N by N compressed-sparse-column or compressed-sparse-row matrix Jac with an approximation to the Jacobian matrix J(t,y) at the point (t,y). Storage for Jac already exists on entry to this function, although the user should ensure that sufficient space is allocated in Jac to hold the nonzero values to be set; if the existing space is insufficient the user may reallocate the data and index arrays as needed. The amount of allocated space in a SUNMATRIX_SPARSE object may be accessed using the macro SM_NNZ_S or the routine SUNSparseMatrix_NNZ. The SUNMATRIX_SPARSE type and accessor macros are documented in §7.3.

4.6.6 Jacobian information (matrix-vector product)

If the CVSPILS solver interface is selected (i.e., CVSpilsSetLinearSolver is called in the steps described in $\S4.4$), the user may provide a function of type CVSpilsJacTimesVecFn in the following form, to compute matrix-vector products Jv. If such a function is not supplied, the default is a difference quotient approximation to these products.

Definition typedef int (*CVSpilsJacTimesVecFn)(N_Vector v, N_Vector Jv, realtype t, N_Vector y, N_Vector fy,

void *user_data, N_Vector tmp);

Purpose This function computes the product $Jv = (\partial f/\partial y)v$ (or an approximation to it).

Arguments v is the vector by which the Jacobian must be multiplied.

Jv is the output vector computed.

t is the current value of the independent variable.

y is the current value of the dependent variable vector.

fy is the current value of the vector f(t, y).

user_data is a pointer to user data, the same as the user_data parameter passed to

 ${\tt CVodeSetUserData}.$

tmp is a pointer to memory allocated for a variable of type N_Vector which can

be used for work space.

Return value The value returned by the Jacobian-vector product function should be 0 if successful.

Any other return value will result in an unrecoverable error of the generic Krylov solver,

in which case the integration is halted.

Notes This function must return a value of J*v that uses the *current* value of J, i.e. as

evaluated at the current (t, y).

If the user's CVSpilsJacTimesVecFn function uses difference quotient approximations, it may need to access quantities not in the argument list. These include the current step size, the error weights, etc. To obtain these, the user will need to add a pointer to cv_mem to user_data and then use the CVodeGet* functions described in §4.5.9.2. The unit roundoff can be accessed as UNIT_ROUNDOFF defined in sundials_types.h.

4.6.7 Jacobian information (matrix-vector setup)

If the user's Jacobian-times-vector requires that any Jacobian-related data be preprocessed or evaluated, then this needs to be done in a user-supplied function of type CVSpilsJacTimesSetupFn, defined as follows:

CVSpilsJacTimesSetupFn

Definition typedef int (*CVSpilsJacTimesSetupFn)(realtype t, N_Vector y, N_Vector fy, void *user_data);

Purpose This function preprocesses and/or evaluates Jacobian-related data needed by the Jacobian-

times-vector routine.

Arguments t is the current value of the independent variable.

y is the current value of the dependent variable vector.

fy is the current value of the vector f(t, y).

user_data is a pointer to user data, the same as the user_data parameter passed to CVodeSetUserData.

OVOGODO OD OT DATE

side.

Return value The value returned by the Jacobian-vector setup function should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

Notes Each call to the Jacobian-vector setup function is preceded by a call to the CVRhsFn user function with the same (t,y) arguments. Thus, the setup function can use any auxiliary data that is computed and saved during the evaluation of the ODE right-hand

If the user's CVSpilsJacTimesSetupFn function uses difference quotient approximations, it may need to access quantities not in the argument list. These include the current step size, the error weights, etc. To obtain these, the user will need to add a pointer

to cv_mem to user_data and then use the CVodeGet* functions described in §4.5.9.2. The unit roundoff can be accessed as UNIT_ROUNDOFF defined in sundials_types.h.

4.6.8 Preconditioning (linear system solution)

If preconditioning is used, then the user must provide a function to solve the linear system Pz=r, where P may be either a left or right preconditioner matrix. Here P should approximate (at least crudely) the matrix $M=I-\gamma J$, where $J=\partial f/\partial y$. If preconditioning is done on both sides, the product of the two preconditioner matrices should approximate M. This function must be of type CVSpilsPrecSolveFn, defined as follows:

```
CVSpilsPrecSolveFn
Definition
              typedef int (*CVSpilsPrecSolveFn)(realtype t, N_Vector y, N_Vector fy,
                                                      N_Vector r, N_Vector z, realtype gamma,
                                                      realtype delta, int lr, void *user_data);
Purpose
              This function solves the preconditioned system Pz = r.
Arguments
                         is the current value of the independent variable.
                         is the current value of the dependent variable vector.
              У
                         is the current value of the vector f(t, y).
              fy
                         is the right-hand side vector of the linear system.
                         is the computed output vector.
                         is the scalar \gamma appearing in the matrix given by M = I - \gamma J.
              gamma
                         is an input tolerance to be used if an iterative method is employed in the
              delta
                         solution. In that case, the residual vector Res = r - Pz of the system should
                         be made less than delta in the weighted l_2 norm, i.e., \sqrt{\sum_i (Res_i \cdot ewt_i)^2} <
                         delta. To obtain the N_Vector ewt, call CVodeGetErrWeights (see §4.5.9.2).
              lr
                         is an input flag indicating whether the preconditioner solve function is to
                         use the left preconditioner (lr = 1) or the right preconditioner (lr = 2);
              user_data is a pointer to user data, the same as the user_data parameter passed to
                         the function CVodeSetUserData.
```

Return value The value returned by the preconditioner solve function is a flag indicating whether it was successful. This value should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

4.6.9 Preconditioning (Jacobian data)

If the user's preconditioner requires that any Jacobian-related data be preprocessed or evaluated, then this needs to be done in a user-supplied function of type CVSpilsPrecSetupFn, defined as follows:

is the current value of the vector f(t, y). fy

jok is an input flag indicating whether the Jacobian-related data needs to be

updated. The jok argument provides for the reuse of Jacobian data in the preconditioner solve function. jok = SUNFALSE means that the Jacobianrelated data must be recomputed from scratch. jok = SUNTRUE means that the Jacobian data, if saved from the previous call to this function, can be reused (with the current value of gamma). A call with jok = SUNTRUE can

only occur after a call with jok = SUNFALSE.

jcurPtr is a pointer to a flag which should be set to SUNTRUE if Jacobian data was

recomputed, or set to SUNFALSE if Jacobian data was not recomputed, but

saved data was still reused.

is the scalar γ appearing in the matrix $M = I - \gamma J$. gamma

user_data is a pointer to user data, the same as the user_data parameter passed to the function CVodeSetUserData.

Return value The value returned by the preconditioner setup function is a flag indicating whether it was successful. This value should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

> The operations performed by this function might include forming a crude approximate Jacobian and performing an LU factorization of the resulting approximation to M= $I - \gamma J$.

Each call to the preconditioner setup function is preceded by a call to the CVRhsFn user function with the same (t,y) arguments. Thus, the preconditioner setup function can use any auxiliary data that is computed and saved during the evaluation of the ODE right-hand side.

This function is not called in advance of every call to the preconditioner solve function, but rather is called only as often as needed to achieve convergence in the nonlinear solver.

If the user's CVSpilsPrecSetupFn function uses difference quotient approximations, it may need to access quantities not in the call list. These include the current step size, the error weights, etc. To obtain these, the user will need to add a pointer to cv_mem to user_data and then use the CVodeGet* functions described in §4.5.9.2. The unit roundoff can be accessed as UNIT_ROUNDOFF defined in sundials_types.h.

4.7Preconditioner modules

The efficiency of Krylov iterative methods for the solution of linear systems can be greatly enhanced through preconditioning. For problems in which the user cannot define a more effective, problemspecific preconditioner, CVODE provides a banded preconditioner in the module CVBANDPRE and a band-block-diagonal preconditioner module CVBBDPRE.

A serial banded preconditioner module 4.7.1

This preconditioner provides a band matrix preconditioner for use with the CVSPILS iterative linear solver interface, in a serial setting. It uses difference quotients of the ODE right-hand side function f to generate a band matrix of bandwidth $m_l + m_u + 1$, where the number of super-diagonals $(m_u, the$ upper half-bandwidth) and sub-diagonals (m_l , the lower half-bandwidth) are specified by the user, and uses this to form a preconditioner for use with the Krylov linear solver. Although this matrix is intended to approximate the Jacobian $\partial f/\partial y$, it may be a very crude approximation. The true Jacobian need not be banded, or its true bandwidth may be larger than $m_l + m_u + 1$, as long as the banded approximation generated here is sufficiently accurate to speed convergence as a preconditioner.

Notes

In order to use the CVBANDPRE module, the user need not define any additional functions. Aside from the header files required for the integration of the ODE problem (see §4.3), to use the CVBANDPRE module, the main program must include the header file cvode_bandpre.h which declares the needed function prototypes. The following is a summary of the usage of this module. Steps that are unchanged from the skeleton program presented in §4.4 are grayed out.

- 1. Initialize multi-threaded environment, if appropriate
- 2. Set problem dimensions
- 3. Set vector of initial values
- 4. Create CVODE object
- 5. Initialize CVODE solver
- 6. Specify integration tolerances
- 7. Set optional inputs
- 8. Create linear solver object

When creating the iterative linear solver object, specify the type of preconditioning (PREC_LEFT or PREC_RIGHT) to use.

- 9. Set linear solver optional inputs
- 10. Attach linear solver module
- 11. Initialize the CVBANDPRE preconditioner module

Specify the upper and lower half-bandwidths (mu and ml, respectively) and call

```
flag = CVBandPrecInit(cvode_mem, N, mu, ml);
```

to allocate memory and initialize the internal preconditioner data.

12. Set linear solver interface optional inputs

Note that the user should not overwrite the preconditioner setup function or solve function through calls to the CVSpilsSetPreconditioner optional input function.

- 13. Specify rootfinding problem
- 14. Advance solution in time
- 15. Get optional outputs

Additional optional outputs associated with CVBANDPRE are available by way of two routines described below, CVBandPrecGetWorkSpace and CVBandPrecGetNumRhsEvals.

- 16. Deallocate memory for solution vector
- 17. Free solver memory
- 18. Free linear solver memory

The CVBANDPRE preconditioner module is initialized and attached by calling the following function:

${\tt CVBandPrecInit}$

Call flag = CVBandPrecInit(cvode_mem, N, mu, ml);

Description The function CVBandPrecInit initializes the CVBANDPRE preconditioner and allocates

required (internal) memory for it.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

N (sunindextype) problem dimension.

mu (sunindextype) upper half-bandwidth of the Jacobian approximation.

ml (sunindextype) lower half-bandwidth of the Jacobian approximation.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The call to CVBandPrecInit was successful.

CVSPILS_MEM_NULL The cvode_mem pointer was NULL.

CVSPILS_MEM_FAIL A memory allocation request has failed.

CVSPILS_LMEM_NULL A CVSPILS linear solver memory was not attached.

CVSPILS_ILL_INPUT The supplied vector implementation was not compatible with block

band preconditioner.

Notes The banded approximate Jacobian will have nonzero elements only in locations (i, j)

with $-ml \le j - i \le mu$.

The following three optional output functions are available for use with the CVBANDPRE module:

CVBandPrecGetWorkSpace

Call flag = CVBandPrecGetWorkSpace(cvode_mem, &lenrwBP, &leniwBP);

 $Description \quad The \ function \ {\tt CVBandPrecGetWorkSpace} \ returns \ the \ sizes \ of \ the \ {\tt CVBANDPRE} \ real \ and \ {\tt CVBANDPRE} \ real \ real$

integer workspaces.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

lenrwBP (long int) the number of realtype values in the CVBANDPRE workspace.

leniwBP (long int) the number of integer values in the CVBANDPRE workspace.

Return value The return value flag (of type int) is one of:

CVSPILS_SUCCESS The optional output values have been successfully set.

CVSPILS_PMEM_NULL The CVBANDPRE preconditioner has not been initialized.

Notes The workspace requirements reported by this routine correspond only to memory al-

located within the CVBANDPRE module (the banded matrix approximation, banded SUNLINSOL object, and temporary vectors).

serialitison object, and temporary vectors).

The workspaces referred to here exist in addition to those given by the corresponding

function CVSpilsGetWorkSpace.

CVBandPrecGetNumRhsEvals

Call flag = CVBandPrecGetNumRhsEvals(cvode_mem, &nfevalsBP);

Description The function CVBandPrecGetNumRhsEvals returns the number of calls made to the

user-supplied right-hand side function for the finite difference banded Jacobian approx-

imation used within the preconditioner setup function.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

nfevalsBP (long int) the number of calls to the user right-hand side function.

Return value The return value flag (of type int) is one of:

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_PMEM_NULL The CVBANDPRE preconditioner has not been initialized.

Notes The counter nfevalsBP is distinct from the counter nfevalsLS returned by the corre-

sponding function CVSpilsGetNumRhsEvals and nfevals returned by CVodeGetNumRhsEvals. The total number of right-hand side function evaluations is the sum of all three of these

counters.

4.7.2 A parallel band-block-diagonal preconditioner module

A principal reason for using a parallel ODE solver such as CVODE lies in the solution of partial differential equations (PDEs). Moreover, the use of a Krylov iterative method for the solution of many such problems is motivated by the nature of the underlying linear system of equations (2.5) that must be solved at each time step. The linear algebraic system is large, sparse, and structured. However, if a Krylov iterative method is to be effective in this setting, then a nontrivial preconditioner needs to be used. Otherwise, the rate of convergence of the Krylov iterative method is usually unacceptably slow. Unfortunately, an effective preconditioner tends to be problem-specific.

However, we have developed one type of preconditioner that treats a rather broad class of PDE-based problems. It has been successfully used for several realistic, large-scale problems [28] and is included in a software module within the CVODE package. This module works with the parallel vector module NVECTOR_PARALLEL and is usable with any of the Krylov iterative linear solvers through the CVSPILS interface. It generates a preconditioner that is a block-diagonal matrix with each block being a band matrix. The blocks need not have the same number of super- and sub-diagonals and these numbers may vary from block to block. This Band-Block-Diagonal Preconditioner module is called CVBBDPRE.

One way to envision these preconditioners is to think of the domain of the computational PDE problem as being subdivided into M non-overlapping subdomains. Each of these subdomains is then assigned to one of the M processes to be used to solve the ODE system. The basic idea is to isolate the preconditioning so that it is local to each process, and also to use a (possibly cheaper) approximate right-hand side function. This requires the definition of a new function g(t,y) which approximates the function f(t,y) in the definition of the ODE system (2.1). However, the user may set g=f. Corresponding to the domain decomposition, there is a decomposition of the solution vector y into M disjoint blocks y_m , and a decomposition of g into blocks g_m . The block g_m depends both on y_m and on components of blocks $y_{m'}$ associated with neighboring subdomains (so-called ghost-cell data). Let \bar{y}_m denote y_m augmented with those other components on which g_m depends. Then we have

$$g(t,y) = [g_1(t,\bar{y}_1), g_2(t,\bar{y}_2), \dots, g_M(t,\bar{y}_M)]^T$$
(4.1)

and each of the blocks $g_m(t, \bar{y}_m)$ is uncoupled from the others.

The preconditioner associated with this decomposition has the form

$$P = diag[P_1, P_2, \dots, P_M] \tag{4.2}$$

where

$$P_m \approx I - \gamma J_m \tag{4.3}$$

and J_m is a difference quotient approximation to $\partial g_m/\partial y_m$. This matrix is taken to be banded, with upper and lower half-bandwidths mudq and mldq defined as the number of non-zero diagonals above and below the main diagonal, respectively. The difference quotient approximation is computed using mudq + mldq +2 evaluations of g_m , but only a matrix of bandwidth mukeep + mlkeep +1 is retained. Neither pair of parameters need be the true half-bandwidths of the Jacobian of the local block of g, if smaller values provide a more efficient preconditioner. The solution of the complete linear system

$$Px = b (4.4)$$

reduces to solving each of the equations

$$P_m x_m = b_m \tag{4.5}$$

and this is done by banded LU factorization of P_m followed by a banded backsolve.

Similar block-diagonal preconditioners could be considered with different treatments of the blocks P_m . For example, incomplete LU factorization or an iterative method could be used instead of banded LU factorization.

The CVBBDPRE module calls two user-provided functions to construct P: a required function gloc (of type CVLocalFn) which approximates the right-hand side function $g(t,y) \approx f(t,y)$ and which is computed locally, and an optional function cfn (of type CVCommFn) which performs all interprocess

communication necessary to evaluate the approximate right-hand side g. These are in addition to the user-supplied right-hand side function f. Both functions take as input the same pointer user_data that is passed by the user to CVodeSetUserData and that was passed to the user's function f. The user is responsible for providing space (presumably within user_data) for components of g that are communicated between processes by g, and that are then used by gloc, which should not do any communication.

CVLocalFn

Definition typedef int (*CVLocalFn)(sunindextype Nlocal, realtype t, N_Vector y, N_Vector glocal, void *user_data);

Purpose This gloc function computes g(t,y). It loads the vector glocal as a function of t and

у.

Arguments Nlocal is the local vector length.

t is the value of the independent variable.

y is the dependent variable. glocal is the output vector.

user_data is a pointer to user data, the same as the user_data parameter passed to CVodeSetUserData.

Return value A CVLocalFn should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODE will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CVode returns CV_LSETUP_FAIL).

This function must assume that all interprocess communication of data needed to calculate glocal has already been done, and that this data is accessible within user_data.

The case where g is mathematically identical to f is allowed.

CVCommFn

Notes

Notes

Definition typedef int (*CVCommFn)(sunindextype Nlocal, realtype t, N_Vector y, void *user_data);

Purpose This cfn function performs all interprocess communication necessary for the execution

of the gloc function above, using the input vector y.

Arguments Nlocal is the local vector length.

t is the value of the independent variable.

y is the dependent variable.

user_data is a pointer to user data, the same as the user_data parameter passed to CVodeSetUserData.

Return value A CVCommFn should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODE will attempt to correct), or a negative value if it failed unrecov-

erably (in which case the integration is halted and CVode returns CV_LSETUP_FAIL).

The cfn function is expected to save communicated data in space defined within the

data structure user_data.

Each call to the cfn function is preceded by a call to the right-hand side function f with the same (t, y) arguments. Thus, cfn can omit any communication done by f if relevant to the evaluation of glocal. If all necessary communication was done in f, then cfn = NULL can be passed in the call to CVBBDPrecInit (see below).

Besides the header files required for the integration of the ODE problem (see §4.3), to use the CVBBDPRE module, the main program must include the header file cvode_bbdpre.h which declares the needed function prototypes.

The following is a summary of the proper usage of this module. Steps that are unchanged from the skeleton program presented in $\S4.4$ are grayed out.

- 1. Initialize MPI environment
- 2. Set problem dimensions
- 3. Set vector of initial values
- 4. Create CVODE object
- 5. Initialize CVODE solver
- 6. Specify integration tolerances
- 7. Set optional inputs

8. Create linear solver object

When creating the iterative linear solver object, specify the type of preconditioning (PREC_LEFT or PREC_RIGHT) to use.

- 9. Set linear solver optional inputs
- 10. Attach linear solver module

11. Initialize the CVBBDPRE preconditioner module

Specify the upper and lower half-bandwidths mudq and mldq, and mukeep and mlkeep, and call

to allocate memory and initialize the internal preconditioner data. The last two arguments of CVBBDPrecInit are the two user-supplied functions described above.

12. Set linear solver interface optional inputs

Note that the user should not overwrite the preconditioner setup function or solve function through calls to the CVSpilsSetPreconditioner optional input function.

13. Advance solution in time

14. Get optional outputs

Additional optional outputs associated with CVBBDPRE are available by way of two routines described below, CVBBDPrecGetWorkSpace and CVBBDPrecGetNumGfnEvals.

- 15. Deallocate memory for solution vector
- 16. Free solver memory
- 17. Free linear solver memory
- 18. Finalize MPI

The user-callable functions that initialize (step 11 above) or re-initialize the CVBBDPRE preconditioner module are described next.

CVBBDPrecInit

```
Call flag = CVBBDPrecInit(cvode_mem, local_N, mudq, mldq, mukeep, mlkeep, dqrely, gloc, cfn);
```

Description The function CVBBDPrecInit initializes and allocates (internal) memory for the CVBB-DPRE preconditioner.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

local_N (sunindextype) local vector length.

mudq (sunindextype) upper half-bandwidth to be used in the difference quotient

Jacobian approximation.

mldq (sunindextype) lower half-bandwidth to be used in the difference quotient

Jacobian approximation.

mukeep (sunindextype) upper half-bandwidth of the retained banded approximate

Jacobian block.

mlkeep (sunindextype) lower half-bandwidth of the retained banded approximate

Jacobian block.

dqrely (realtype) the relative increment in components of y used in the difference

quotient approximations. The default is $dqrely = \sqrt{unit roundoff}$, which

can be specified by passing dqrely = 0.0.

gloc (CVLocalFn) the C function which computes the approximation $g(t,y) \approx$

f(t,y).

cfn (CVCommFn) the optional C function which performs all interprocess commu-

nication required for the computation of g(t, y).

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The call to CVBBDPrecInit was successful.

CVSPILS_MEM_NULL The cvode_mem pointer was NULL.

CVSPILS_MEM_FAIL A memory allocation request has failed.

CVSPILS_LMEM_NULL A CVSPILS linear solver was not attached.

CVSPILS_ILL_INPUT The supplied vector implementation was not compatible with block

band preconditioner.

Notes

If one of the half-bandwidths mudq or mldq to be used in the difference quotient calculation of the approximate Jacobian is negative or exceeds the value local_N-1, it is replaced by 0 or local_N-1 accordingly.

The half-bandwidths mudq and mldq need not be the true half-bandwidths of the Jacobian of the local block of g when smaller values may provide a greater efficiency.

Also, the half-bandwidths mukeep and mlkeep of the retained banded approximate Jacobian block may be even smaller, to reduce storage and computational costs further.

For all four half-bandwidths, the values need not be the same on every processor.

The CVBBDPRE module also provides a reinitialization function to allow solving a sequence of problems of the same size, with the same linear solver choice, provided there is no change in local_N, mukeep, or mlkeep. After solving one problem, and after calling CVodeReInit to re-initialize CVODE for a subsequent problem, a call to CVBBDPrecReInit can be made to change any of the following: the half-bandwidths mudq and mldq used in the difference-quotient Jacobian approximations, the relative increment dqrely, or one of the user-supplied functions gloc and cfn. If there is a change in any of the linear solver inputs, an additional call to the "Set" routines provided by the SUNLINSOL module, and/or one or more of the corresponding CVSpilsSet*** functions, must also be made (in the proper order).

CVBBDPrecReInit

Call flag = CVBBDPrecReInit(cvode_mem, mudq, mldq, dqrely);

Description The function CVBBDPrecReInit re-initializes the CVBBDPRE preconditioner.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

mudq (sunindextype) upper half-bandwidth to be used in the difference quotient Jacobian approximation.

mu

mldq (sunindextype) lower half-bandwidth to be used in the difference quotient

Jacobian approximation.

dqrely (realtype) the relative increment in components of y used in the difference

quotient approximations. The default is $dqrely = \sqrt{unit roundoff}$, which

can be specified by passing dqrely = 0.0.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The call to CVBBDPrecReInit was successful.

CVSPILS_MEM_NULL The cvode_mem pointer was NULL.

CVSPILS_LMEM_NULL A CVSPILS linear solver memory was not attached.

CVSPILS_PMEM_NULL The function CVBBDPrecInit was not previously called.

Notes If one of the half-bandwidths mudq or mldq is negative or exceeds the value local_N-1,

it is replaced by 0 or local_N-1 accordingly.

The following two optional output functions are available for use with the CVBBDPRE module:

CVBBDPrecGetWorkSpace

Call flag = CVBBDPrecGetWorkSpace(cvode_mem, &lenrwBBDP, &leniwBBDP);

Description The function CVBBDPrecGetWorkSpace returns the local CVBBDPRE real and integer

workspace sizes.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

lenrwBBDP (long int) local number of realtype values in the CVBBDPRE workspace.

leniwBBDP (long int) local number of integer values in the CVBBDPRE workspace.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer was NULL.

CVSPILS_PMEM_NULL The CVBBDPRE preconditioner has not been initialized.

Notes The workspace requirements reported by this routine correspond only to memory allo-

cated within the CVBBDPRE module (the banded matrix approximation, banded SUN-

LINSOL object, temporary vectors). These values are local to each process.

The workspaces referred to here exist in addition to those given by the corresponding

function CVSpilsGetWorkSpace.

CVBBDPrecGetNumGfnEvals

Call flag = CVBBDPrecGetNumGfnEvals(cvode_mem, &ngevalsBBDP);

Description The function CVBBDPrecGetNumGfnEvals returns the number of calls made to the user-

supplied gloc function due to the finite difference approximation of the Jacobian blocks

used within the preconditioner setup function.

Arguments cvode_mem (void *) pointer to the CVODE memory block.

ngevalsBBDP (long int) the number of calls made to the user-supplied gloc function.

Return value The return value flag (of type int) is one of

CVSPILS_SUCCESS The optional output value has been successfully set.

CVSPILS_MEM_NULL The cvode_mem pointer was NULL.

CVSPILS_PMEM_NULL The CVBBDPRE preconditioner has not been initialized.

In addition to the ngevalsBBDP gloc evaluations, the costs associated with CVBBDPRE also include nlinsetups LU factorizations, nlinsetups calls to cfn, npsolves banded backsolve calls, and nfevalsLS right-hand side function evaluations, where nlinsetups is an optional CVODE output and npsolves and nfevalsLS are linear solver optional outputs (see §4.5.9).

Chapter 5

FCVODE, an Interface Module for FORTRAN Applications

The fcvode interface module is a package of C functions which support the use of the cvode solver, for the solution of ODE systems dy/dt = f(t,y), in a mixed Fortran/C setting. While cvode is written in C, it is assumed here that the user's calling program and user-supplied problem-defining routines are written in Fortran. This package provides the necessary interface to cvode for all supplied serial and parallel NVECTOR implementations.

5.1 Important note on portability

In this package, the names of the interface functions, and the names of the FORTRAN user routines called by them, appear as dummy names which are mapped to actual values by a series of definitions in the header files. By default, those mapping definitions depend in turn on the C macro F77_FUNC defined in the header file sundials_config.h. The mapping defined by F77_FUNC in turn transforms the C interface names to match the name-mangling approach used by the supplied Fortran compiler.

By "name-mangling", we mean that due to the case-independent nature of the FORTRAN language, FORTRAN compilers convert all subroutine and object names to use either all lower-case or all upper-case characters, and append either zero, one or two underscores as a prefix or suffix to the name. For example, the FORTRAN subroutine MyFunction() will be changed to one of myfunction, MYFUNCTION, myfunction__, MYFUNCTION_, and so on, depending on the FORTRAN compiler used.

SUNDIALS determines this name-mangling scheme at configuration time (see Appendix A).

5.2 Fortran Data Types

Throughout this documentation, we will refer to data types according to their usage in C. The equivalent types to these may vary, depending on your computer architecture and on how SUNDIALS was compiled (see Appendix A). A FORTRAN user should first determine the equivalent types for their architecture and compiler, and then take care that all arguments passed through this FORTRAN/C interface are declared of the appropriate type.

Integers: While SUNDIALS uses the configurable sunindextype type as the integer type for vector and matrix indices for its C code, the FORTRAN interfaces are more restricted. The sunindextype is only used for index values and pointers when filling sparse matrices. As for C, the sunindextype can be configured to be a 32- or 64-bit signed integer by setting the variable SUNDIALS_INDEX_TYPE at compile time (See Appendix A). The default value is int64_t. A FORTRAN user should set this variable based on the integer type used for vector and matrix indices in their FORTRAN code. The corresponding FORTRAN types are:

• int64_t - equivalent to an INTEGER*8 in FORTRAN

In general, for the FORTRAN interfaces in SUNDIALS, flags of type int, vector and matrix lengths, counters, and arguments to *SETIN() functions all have long int type, and sunindextype is only used for index values and pointers when filling sparse matrices. Note that if an F90 (or higher) user wants to find out the value of sunindextype, they can include sundials_fconfig.h.

Real numbers: As discussed in Appendix A, at compilation SUNDIALS allows the configuration option SUNDIALS_PRECISION, that accepts values of single, double or extended (the default is double). This choice dictates the size of a realtype variable. The corresponding FORTRAN types for these realtype sizes are:

- single equivalent to a REAL or REAL*4 in FORTRAN
- double equivalent to a DOUBLE PRECISION or REAL*8 in FORTRAN
- extended equivalent to a REAL*16 in FORTRAN

5.3 FCVODE routines

The user-callable functions, with the corresponding CVODE functions, are as follows:

- Interface to the NVECTOR modules
 - FNVINITS (defined by NVECTOR_SERIAL) interfaces to N_VNewEmpty_Serial.
 - FNVINITP (defined by NVECTOR_PARALLEL) interfaces to N_VNewEmpty_Parallel.
 - FNVINITOMP (defined by NVECTOR_OPENMP) interfaces to N_VNewEmpty_OpenMP.
 - FNVINITPTS (defined by NVECTOR_PTHREADS) interfaces to N_VNewEmpty_Pthreads.
- Interface to the SUNMATRIX modules
 - FSUNBANDMATINIT (defined by SUNMATRIX_BAND) interfaces to SUNBandMatrix.
 - FSUNDENSEMATINIT (defined by SUNMATRIX_DENSE) interfaces to SUNDenseMatrix.
 - FSUNSPARSEMATINIT (defined by SUNMATRIX_SPARSE) interfaces to SUNSparseMatrix.
- Interface to the SUNLINSOL modules
 - FSUNBANDLINSOLINIT (defined by SUNLINSOL_BAND) interfaces to SUNBandLinearSolver.
 - FSUNDENSELINSOLINIT (defined by SUNLINSOL_DENSE) interfaces to SUNDenseLinearSolver.
 - FSUNKLUINIT (defined by SUNLINSOL_KLU) interfaces to SUNKLU.
 - FSUNKLUREINIT (defined by SUNLINSOL_KLU) interfaces to SUNKLUReinit.
 - FSUNLAPACKBANDINIT (defined by SUNLINSOL_LAPACKBAND) interfaces to SUNLapackBand.
 - FSUNLAPACKDENSEINIT (defined by SUNLINSOL_LAPACKDENSE) interfaces to SUNLapackDense.
 - FSUNPCGINIT (defined by SUNLINSOL_PCG) interfaces to SUNPCG.
 - FSUNSPBCGSINIT (defined by SUNLINSOL_SPBCGS) interfaces to SUNSPBCGS.
 - FSUNSPFGMRINIT (defined by SUNLINSOL_SPFGMR) interfaces to SUNSPFGMR.
 - FSUNSPGMRINIT (defined by SUNLINSOL_SPGMR) interfaces to SUNSPGMR.
 - FSUNSPTFQMRINIT (defined by SUNLINSOL_SPTFQMR) interfaces to SUNSPTFQMR.
 - FSUNSUPERLUMTINIT (defined by SUNLINSOL_SUPERLUMT) interfaces to SUNSuperLUMT.
- Interface to the main CVODE module
 - FCVMALLOC interfaces to CVodeCreate, CVodeSetUserData, and CVodeInit, as well as one of CVodeSStolerances or CVodeSVtolerances.

- FCVREINIT interfaces to CVodeReInit.
- FCVSETIIN and FCVSETRIN interface to CVodeSet* functions.
- FCVEWTSET interfaces to CVodeWFtolerances.
- FCVODE interfaces to CVode, CVodeGet* functions, and to the optional output functions for the selected linear solver module.
- FCVDKY interfaces to the interpolated output function CVodeGetDky.
- FCVGETERRWEIGHTS interfaces to CVodeGetErrWeights.
- FCVGETESTLOCALERR interfaces to CVodeGetEstLocalErrors.
- FCVFREE interfaces to CVodeFree.
- Interface to the linear solver interfaces
 - FCVDLSINIT interfaces to CVDlsSetLinearSolver.
 - FCVDENSESETJAC interfaces to CVDlsSetJacFn.
 - FCVBANDSETJAC interfaces to CVDlsSetJacFn.
 - FCVSPARSESETJAC interfaces to CVDlsSetJacFn.
 - FCVSPILSINIT interfaces to CVSpilsSetLinearSolver.
 - FCVSPILSSETEPSLIN interfaces to CVSpilsSetEpsLin.
 - FCVSPILSSETJAC interfaces to CVSpilsSetJacTimes.
 - FCVSPILSSETPREC interfaces to CVSpilsSetPreconditioner.
 - FCVDIAG interfaces to CVDiag.
- Interface to the nonlinear solver interface
 - FCVNLSINIT interfaces to CVSetNonlinearSolver.

The user-supplied functions, each listed with the corresponding internal interface function which calls it (and its type within CVODE), are as follows:

FCVODE routine	CVODE function	CVODE type of
(FORTRAN, user-supplied)	(C, interface)	interface function
FCVFUN	FCVf	CVRhsFn
FCVEWT	FCVEwtSet	CVEwtFn
FCVDJAC	FCVDenseJac	CVDlsJacFn
FCVBJAC	FCVBandJac	CVDlsJacFn
FCVSPJAC	FCVSparseJac	CVDlsJacFn
FCVPSOL	FCVPSol	CVSpilsPrecSolveFn
FCVPSET	FCVPSet	CVSpilsPrecSetupFn
FCVJTIMES	FCVJtimes	CVSpilsJacTimesVecFn
FCVJTSETUP	FCVJTSetup	CVSpilsJacTimesSetupFn

In contrast to the case of direct use of CVODE, and of most FORTRAN ODE solvers, the names of all user-supplied routines here are fixed, in order to maximize portability for the resulting mixed-language program.

5.4 Usage of the FCVODE interface module

The usage of FCVODE requires calls to a variety of interface functions, depending on the method options selected, and one or more user-supplied routines which define the problem to be solved. These function calls and user routines are summarized separately below. Some details are omitted, and the user is referred to the description of the corresponding CVODE functions for information on the arguments of any given user-callable interface routine, or of a given user-supplied function called by an interface function. The usage of FCVODE for rootfinding and with preconditioner modules is described in later subsections.

1. Right-hand side specification

The user must, in all cases, supply the following FORTRAN routine

```
SUBROUTINE FCVFUN(T, Y, YDOT, IPAR, RPAR, IER)
DIMENSION Y(*), YDOT(*), IPAR(*), RPAR(*)
```

It must set the YDOT array to f(t,y), the right-hand side of the ODE system, as function of T=t and the array Y=y. The arrays IPAR (of integers) and RPAR (of reals) contain user data and are the same as those passed to FCVMALLOC. IER is an error return flag which should be set to 0 if successful, a positive value if a recoverable error occurred (in which case CVODE will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted).

2. NVECTOR module initialization

If using one of the NVECTOR modules supplied with SUNDIALS, the user must make a call of the form

```
CALL FNVINIT***(...)
```

in which the name and call sequence are as described in the appropriate section of Chapter 6.

3. SUNMATRIX module initialization

If using a nonlinear solver that requires a linear solver (e.g., the default Newton iteration) and the linear solver is a direct linear solver, then one of the SUNMATRIX modules supplied with SUNDIALS, the user must make a call of the form

```
CALL FSUN***MATINIT(...)
```

in which the name and call sequence are as described in the appropriate section of Chapter 7. Note that the dense, band, or sparse matrix options are usable only in a serial or multi-threaded environment.

4. SUNLINSOL module initialization

If using a nonlinear solver that requires a linear solver (e.g., the default Newton iteration) and one of the SUNLINSOL linear solver modules supplied with SUNDIALS, the user must make a call of the form

```
CALL FSUNBANDLINSOLINIT(...)

CALL FSUNCHUINIT(...)

CALL FSUNKLUINIT(...)

CALL FSUNLAPACKBANDINIT(...)

CALL FSUNLAPACKDENSEINIT(...)

CALL FSUNSPBCGSINIT(...)

CALL FSUNSPFGMRINIT(...)

CALL FSUNSPFGMRINIT(...)

CALL FSUNSPFGMRINIT(...)

CALL FSUNSPFGMRINIT(...)

CALL FSUNSPFFQMRINIT(...)
```

in which the call sequence is as described in the appropriate section of Chapter 8. Note that the dense, band, or sparse solvers are usable only in a serial or multi-threaded environment.

Once one of these has been initialized, its solver parameters may be modified using a call to the functions

```
CALL FSUNKLUSETORDERING(...)

CALL FSUNSUPERLUMTSETORDERING(...)

CALL FSUNPCGSETPRECTYPE(...)

CALL FSUNSPBCGSSETMAXL(...)

CALL FSUNSPBCGSSETMAXL(...)

CALL FSUNSPFGMRSETGSTYPE(...)

CALL FSUNSPFGMRSETPRECTYPE(...)

CALL FSUNSPFGMRSETGSTYPE(...)

CALL FSUNSPFGMRSETPRECTYPE(...)

CALL FSUNSPFGMRSETPRECTYPE(...)

CALL FSUNSPFGMRSETPRECTYPE(...)

CALL FSUNSPTFQMRSETPRECTYPE(...)

CALL FSUNSPTFQMRSETPRECTYPE(...)
```

where again the call sequences are described in the appropriate sections of Chapter 8.

5. SUNNONLINSOL module initialization

By default CVODE uses the SUNNONLINSOL implementation of Newton's method defined by the SUNNONLINSOL_NEWTON module (see §9.2). To specify a non-default nonlinear solver in CVODE, the user's program must create a SUNNONLINSOL object by calling the appropriate Fortran interface function to the constructor routine (see Chapter 9). For example, to create the SUNNONLINSOL_FIXEDPOINT solver call the function

```
CALL FSUNFIXEDPOINTINIT(...)
```

in which the call sequence is described in §9.3.

6. Problem specification

To set various problem and solution parameters and allocate internal memory, make the following call:

FCVMALLOC

```
Call
               CALL FCVMALLOC(TO, YO, METH, IATOL, RTOL, ATOL,
                                 IOUT, ROUT, IPAR, RPAR, IER)
             This function provides required problem and solution specifications, specifies op-
Description
              tional inputs, allocates internal memory, and initializes CVODE.
                     is the initial value of t.
Arguments
             TΩ
              YΟ
                     is an array of initial conditions.
             METH specifies the basic integration method: 1 for Adams (nonstiff) or 2 for BDF
              IATOL specifies the type for absolute tolerance ATOL: 1 for scalar or 2 for array. If
                     IATOL = 3, the arguments RTOL and ATOL are ignored and the user is expected
                     to subsequently call FCVEWTSET and provide the function FCVEWT.
             RTOL
                    is the relative tolerance (scalar).
                    is the absolute tolerance (scalar or array).
                    is an integer array of length 21 for integer optional outputs.
                    is a real array of length 6 for real optional outputs.
             ROUT
              IPAR
                    is an integer array of user data which will be passed unmodified to all user-
                     provided routines.
              RPAR is a real array of user data which will be passed unmodified to all user-
                     provided routines.
```

Return value IER is a return completion flag. Values are 0 for successful return and -1 otherwise. See printed message for details in case of failure.

Notes

The user integer data arrays IOUT and IPAR must be declared as INTEGER*4 or INTEGER*8 according to the C type long int.

Modifications to the user data arrays IPAR and RPAR inside a user-provided routine will be propagated to all subsequent calls to such routines.

The optional outputs associated with the main CVODE integrator are listed in Table 5.2.

As an alternative to providing tolerances in the call to FCVMALLOC, the user may provide a routine to compute the error weights used in the WRMS norm evaluations. If supplied, it must have the following form:

```
SUBROUTINE FCVEWT (Y, EWT, IPAR, RPAR, IER)
DIMENSION Y(*), EWT(*), IPAR(*), RPAR(*)
```

It must set the positive components of the error weight vector EWT for the calculation of the WRMS norm of Y. On return, set IER = 0 if FCVEWT was successful, and nonzero otherwise. The arrays IPAR (of integers) and RPAR (of reals) contain user data and are the same as those passed to FCVMALLOC.

If the FCVEWT routine is provided, then, following the call to FCVMALOC, the user must make the call:

```
CALL FCVEWTSET (FLAG, IER)
```

with $FLAG \neq 0$ to specify use of the user-supplied error weight routine. The argument IER is an error return flag which is 0 for success or non-zero if an error occurred.

7. Set optional inputs

Call FCVINSETIIN and/or FCVINSETRIN to set desired optional inputs, if any. See §5.5 for details.

8. Linear solver interface specification

To attach the linear solver (and optionally the matrix) objects initialized in steps 3 and 4 above, the user of FCVODE must initialize the CVDLS or CVSPILS linear solver interface.

CVDLS direct linear solver interface

To attach a direct SUNLINSOL object and corresponding SUNMATRIX object to the CVDLS interface, then following calls to initialize the SUNLINSOL and SUNMATRIX objects in steps 3 and 4 above, the user must make the call:

```
CALL FCVDLSINIT(IER)
```

IER is an error return flag set on 0 on success or -1 if a memory failure occurred.

Optional outputs specific to the CVDLS case are listed in Table 5.2.

CVDLS with dense Jacobian matrix As an option when using the CVDLS interface with SUN-LINSOL_DENSE or SUNLINSOL_LAPACKDENSE linear solvers, the user may supply a routine that computes a dense approximation of the system Jacobian $J = \partial f/\partial y$. If supplied, it must have the following form:

```
SUBROUTINE FCVDJAC (NEQ, T, Y, FY, DJAC, H, IPAR, RPAR, & WK1, WK2, WK3, IER)

DIMENSION Y(*), FY(*), DJAC(NEQ,*), IPAR(*), RPAR(*), 

WK1(*), WK2(*), WK3(*)
```

Typically this routine will use only NEQ, T, Y, and DJAC. It must compute the Jacobian and store it columnwise in DJAC. The input arguments T, Y, and FY contain the current values of t, y, and f(t,y), respectively. The arrays IPAR (of integers) and RPAR (of reals) contain user data and are the same as those passed to FCVMALLOC. The vectors WK1, WK2, and WK3 of length NEQ are provided as work space for use in FCVDJAC. IER is an error return flag which should be set to 0 if successful, a positive value if a recoverable error occurred (in which case CVODE will attempt to correct), or a negative value if FCVDJAC failed unrecoverably (in which case the integration is halted). NOTE: The argument NEQ has a type consistent with C type long int even in the case when the LAPACK dense solver is to be used.

If the user's FCVDJAC uses difference quotient approximations, it may need to use the error weight array EWT and current stepsize H in the calculation of suitable increments. The array EWT can be obtained by calling FCVGETERRWEIGHTS using one of the work arrays as temporary storage for EWT. It may also need the unit roundoff, which can be obtained as the optional output ROUT(6), passed from the calling program to this routine using either RPAR or a common block.

If the FCVDJAC routine is provided, then, following the call to FCVDLSINIT, the user must make the call:

```
CALL FCVDENSESETJAC (FLAG, IER)
```

with $FLAG \neq 0$ to specify use of the user-supplied Jacobian approximation. The argument IER is an error return flag which is 0 for success or non-zero if an error occurred.

CVDLS with band Jacobian matrix As an option when using the CVDLS interface with SUNLIN-SOL_BAND or SUNLINSOL_LAPACKBAND linear solvers, the user may supply a routine that computes a band approximation of the system Jacobian $J = \partial f/\partial y$. If supplied, it must have the following form:

```
SUBROUTINE FCVBJAC(NEQ, MU, ML, MDIM, T, Y, FY, BJAC, H, IPAR, RPAR, & WK1, WK2, WK3, IER)

DIMENSION Y(*), FY(*), BJAC(MDIM,*), IPAR(*), RPAR(*), 
& WK1(*), WK2(*), WK3(*)
```

Typically this routine will use only NEQ, MU, ML, T, Y, and BJAC. It must load the MDIM by N array BJAC with the Jacobian matrix at the current (t,y) in band form. Store in BJAC(k,j) the Jacobian element $J_{i,j}$ with k=i-j+ MU +1 $(k=1\cdots$ ML + MU + 1) and $j=1\cdots N$. The input arguments T, Y, and FY contain the current values of t,y, and f(t,y), respectively. The arrays IPAR (of integers) and RPAR (of reals) contain user data and are the same as those passed to FCVMALLOC. The vectors WK1, WK2, and WK3 of length NEQ are provided as work space for use in FCVBJAC. IER is an error return flag which should be set to 0 if successful, a positive value if a recoverable error occurred (in which case CVODE will attempt to correct), or a negative value if FCVBJAC failed unrecoverably (in which case the integration is halted). NOTE: The arguments NEQ, MU, ML, and MDIM have a type consistent with C type long int even in the case when the LAPACK band solver is to be used.

If the user's FCVBJAC uses difference quotient approximations, it may need to use the error weight array EWT and current stepsize H in the calculation of suitable increments. The array EWT can be obtained by calling FCVGETERRWEIGHTS using one of the work arrays as temporary storage for EWT. It may also need the unit roundoff, which can be obtained as the optional output ROUT(6), passed from the calling program to this routine using either RPAR or a common block.

If the FCVBJAC routine is provided, then, following the call to FCVDLSINIT, the user must make the call:

with FLAG $\neq 0$ to specify use of the user-supplied Jacobian approximation. The argument IER is an error return flag which is 0 for success or non-zero if an error occurred.

CVDLS with sparse Jacobian matrix When using the CVDLS interface with SUNLINSOL_KLU or SUNLINSOL_SUPERLUMT linear solvers, the user must supply the FCVSPJAC routine that computes a compressed-sparse-column or compressed-sparse-row if using KLU approximation of the system Jacobian $J = \partial f/\partial y$. If supplied, it must have the following form:

```
SUBROUTINE FCVSPJAC(T, Y, FY, N, NNZ, JDATA, JINDEXVALS, & JINDEXPTRS, H, IPAR, RPAR, WK1, WK2, WK3, IER)
```

It must load the N by N compressed sparse column [or compressed sparse row] matrix with storage for NNZ nonzeros, stored in the arrays JDATA, JINDEXVALS and JINDEXPTRS, with the Jacobian matrix at the current (t,y) in CSC [or CSR] form (see summatrix_sparse.h for more information). The arguments are T, the current time; Y, an array containing state variables; FY, an array containing state derivatives; N, the number of matrix rows/columns in the Jacobian; NNZ, allocated length of nonzero storage; JDATA, nonzero values in the Jacobian (of length NNZ); JINDEXVALS, row [or column] indices for each nonzero in Jacobian (of length NNZ); JINDEXPTRS, pointers to each Jacobian column [or row] in the two preceding arrays (of length N+1); H, the current step size; IPAR, an array containing integer user data that was passed to FCVMALLOC; RPAR, an array containing real user data that was passed to FCVMALLOC; WK*, work arrays containing temporary workspace of same size as Y; and IER, error return code (0 if successful, > 0 if a recoverable error occurred, or < 0 if an unrecoverable error occurred.)

To indicate that the FCVSPJAC routine has been provided, then following the call to FCVDLSINIT, the following call must be made

```
CALL FCVSPARSESETJAC (IER)
```

The int return flag IER is an error return flag which is 0 for success or nonzero for an error.

CVSPILS iterative linear solver interface

To attach an iterative SUNLINSOL object to the CVSPILS interface, then following the call to initialize the SUNLINSOL object in step 4 above, the user must make the call:

```
CALL FCVSPILSINIT(IER)
```

IER is an error return flag set on 0 on success or -1 if a memory failure occurred.

Optional outputs specific to the CVSPILS case are listed in Table 5.2.

Functions used by CVSPILS

Optional user-supplied routines FCVJTIMES and FCVJTSETUP (see below), can be provided for Jacobian-vector products. If they are, then, following the call to FCVSPILSINIT, the user must make the call:

```
CALL FCVSPILSSETJAC(FLAG, IER)
```

with $FLAG \neq 0$ to specify use of the user-supplied Jacobian-times-vector setup and product routines. The argument IER is an error return flag which is 0 for success or non-zero if an error occurred.

If preconditioning is to be done, then the user must call

```
CALL FCVSPILSSETPREC(FLAG, IER)
```

with $FLAG \neq 0$. The return flag IER is 0 if successful, or negative if a memory error occurred. In addition, the user program must include preconditioner routines FCVPSOL and FCVPSET (see below).

User-supplied routines for CVSPILS

With treatment of the linear systems by any of the Krylov iterative solvers, there are four optional user-supplied routines — FCVJTIMES, FCVJTSETUP, FCVPSOL, and FCVPSET. The specifications for these routines are given below.

As an option when using the CVSPILS linear solver interface, the user may supply a routine that computes the product of the system Jacobian $J = \partial f/\partial y$ and a given vector v. If supplied, it must have the following form:

```
SUBROUTINE FCVJTIMES (V, FJV, T, Y, FY, H, IPAR, RPAR, WORK, IER)
DIMENSION V(*), FJV(*), Y(*), FY(*), IPAR(*), RPAR(*), WORK(*)
```

Typically this routine will use only T, Y, V, and FJV. It must compute the product vector Jv, where the vector v is stored in V, and store the product in FJV. The input arguments T, Y, and FY contain the current values of t, y, and f(t,y), respectively. On return, set IER = 0 if FCVJTIMES was successful, and nonzero otherwise. The arrays IPAR (of integers) and RPAR (of reals) contain user data and are the same as those passed to FCVMALLOC. The vector WORK, of length commensurate with the input YO to FCVMALLOC, is provided as work space for use in FCVJTIMES.

If the user's Jacobian-times-vector product routine requires that any Jacobian related data be evaluated or preprocessed, then the following routine can be used for the evaluation and preprocessing of this data:

```
SUBROUTINE FCVJTSETUP (T, Y, FY, H, IPAR, RPAR, IER) DIMENSION Y(*), FY(*), IPAR(*), RPAR(*)
```

Typically this routine will use only T and Y. It should compute any necessary data for subsequent calls to FCVJTIMES. On return, set IER = 0 if FCVJTSETUP was successful, and nonzero otherwise. The arrays IPAR (of integers) and RPAR (of reals) contain user data and are the same as those passed to FCVMALLOC.

If the user calls FCVSPILSSETJAC, the routine FCVJTSETUP must be provided, even if it is not needed, and it must return IER=0.

If preconditioning is to be included, the following routine must be supplied, for solution of the preconditioner linear system:

```
SUBROUTINE FCVPSOL(T, Y, FY, R, Z, GAMMA, DELTA, LR, IPAR, RPAR, IER) DIMENSION Y(*), FY(*), R(*), Z(*), IPAR(*), RPAR(*)
```

It must solve the preconditioner linear system Pz=r, where r=R is input, and store the solution z in Z. Here P is the left preconditioner if LR=1 and the right preconditioner if LR=2. The preconditioner (or the product of the left and right preconditioners if both are nontrivial) should be an approximation to the matrix $I-\gamma J$, where I is the identity matrix, J is the system Jacobian, and $\gamma=\text{GAMMA}$. The input arguments T, Y, and FY contain the current values of t,y, and f(t,y), respectively. On return, set IER = 0 if FCVPSOL was successful, set IER positive if a recoverable error occurred, and set IER negative if a non-recoverable error occurred.

The arrays IPAR (of integers) and RPAR (of reals) contain user data and are the same as those passed to FCVMALLOC.

If the user's preconditioner requires that any Jacobian related data be evaluated or preprocessed, then the following routine can be used for the evaluation and preprocessing of the preconditioner:

```
SUBROUTINE FCVPSET(T, Y, FY, JOK, JCUR, GAMMA, H, IPAR, RPAR, IER) DIMENSION Y(*), FY(*), EWT(*), IPAR(*), RPAR(*)
```

It must perform any evaluation of Jacobian-related data and preprocessing needed for the solution of the preconditioner linear systems by FCVPSOL. The input argument JOK allows for Jacobian data to be saved and reused: If JOK = 0, this data should be recomputed from scratch. If JOK = 1, a saved copy of it may be reused, and the preconditioner constructed from it. The input arguments T, Y, and FY contain the current values of t, y, and f(t,y), respectively. On return, set JCUR = 1 if Jacobian data was computed, and set JCUR = 0 otherwise. Also on return, set IER = 0 if FCVPSET was successful, set IER positive if a recoverable error occurred, and set IER negative if a non-recoverable error occurred.

The arrays IPAR (of integers) and RPAR (of reals) contain user data and are the same as those passed to FCVMALLOC.

Notes

- (a) If the user's FCVJTIMES or FCVPSET routine uses difference quotient approximations, it may need to use the error weight array EWT, the current stepsize H, and/or the unit roundoff, in the calculation of suitable increments. Also, If FCVPSOL uses an iterative method in its solution, the residual vector $\rho = r Pz$ of the system should be made less than DELTA in weighted ℓ_2 norm, i.e. $\sqrt{\sum (\rho_i * \text{EWT}[i])^2} < \text{DELTA}$.
- (b) If needed in FCVJTIMES, FCVJTSETUP, FCVPSOL, or FCVPSET, the error weight array EWT can be obtained by calling FCVGETERRWEIGHTS using a user-allocated array as temporary storage for EWT.
- (c) If needed in FCVJTIMES, FCVJTSETUP, FCVPSOL, or FCVPSET, the unit roundoff can be obtained as the optional output ROUT(6) (available after the call to FCVMALLOC) and can be passed using either the RPAR user data array, a common block or a module.

CVDIAG diagonal linear solver interface

CVODE is also packaged with a CVODE-specific diagonal approximate Jacobian and linear solver interface. This choice is appropriate when the Jacobian can be well approximated by a diagonal matrix. The user must make the call:

CALL FCVDIAG(IER)

IER is an error return flag set on 0 on success or -1 if a memory failure occurred.

There are no additional user-supplied routines for the CVDIAG interface.

Optional outputs specific to the CVDIAG case are listed in Table 5.2.

9. Nonlinear solver interface specification

If a non-default SUNNONLINSOL object was created in step 5, the user must attach it to CVODE with the call:

CALL FCVNLSINIT(IER)

IER is an error return flag set on 0 on success or -1 if an error occurred.

Once attached, the user may specify non-default inputs for the SUNNONLINSOL object (e.g. the maximum number of nonlinear iterations) by calling appropriate Fortran interface routines (see Chapter 9).

10. Problem solution

Carrying out the integration is accomplished by making calls as follows:

```
CALL FCVODE(TOUT, T, Y, ITASK, IER)
```

The arguments are as follows. TOUT specifies the next value of t at which a solution is desired (input). T is the value of t reached by the solver on output. Y is an array containing the computed solution on output. ITASK is a task indicator and should be set to 1 for normal mode (overshoot TOUT and interpolate), or to 2 for one-step mode (return after each internal step taken). IER is a completion flag and will be set to a positive value upon successful return or to a negative value if an error occurred. These values correspond to the CVode returns (see §4.5.6 and §B.2). The current values of the optional outputs are available in IOUT and ROUT (see Table 5.2).

11. Additional solution output

After a successful return from FCVODE, the routine FCVDKY may be used to obtain a derivative of the solution, of order up to the current method order, at any t within the last step taken. For this, make the following call:

```
CALL FCVDKY(T, K, DKY, IER)
```

where T is the value of t at which solution derivative is desired, and K is the derivative order $(0 \le K \le QU)$. On return, DKY is an array containing the computed K-th derivative of y. The value T must lie between TCUR - HU and TCUR. The return flag IER is set to 0 upon successful return or to a negative value to indicate an illegal input.

12. Problem reinitialization

To re-initialize the CVODE solver for the solution of a new problem of the same size as one already solved, make the following call:

```
CALL FCVREINIT(TO, YO, IATOL, RTOL, ATOL, IER)
```

The arguments have the same names and meanings as those of FCVMALLOC. FCVREINIT performs the same initializations as FCVMALLOC, but does no memory allocation, using instead the existing internal memory created by the previous FCVMALLOC call. The call to specify the linear system solution method may or may not be needed.

Following this call, if the choice of linear solver is being changed then a user must make a call to create the alternate SUNLINSOL module and then attach it to the CVDLS or CVSPILS interface, as shown above. If only linear solver parameters are being modified, then these calls may be made without re-attaching to the CVDLS or CVSPILS interface.

13. Memory deallocation

To free the internal memory created by the call to FCVMALLOC, FCVDLSINIT/FCVSPILSINIT, FNVINIT* and FSUN***MATINIT, make the call

CALL FCVFREE

5.5 FCVODE optional input and output

In order to keep the number of user-callable FCVODE interface routines to a minimum, optional inputs to the CVODE solver are passed through only two routines: FCVSETIIN for integer optional inputs and FCVSETRIN for real optional inputs. These functions should be called as follows:

```
CALL FCVSETIIN(KEY, IVAL, IER)
CALL FCVSETRIN(KEY, RVAL, IER)
```

Integer optional inputs (FCVSETIIN)		
Key	Optional input	Default value
MAX_ORD	Maximum LMM method order	5 (BDF), 12 (Adams)
MAX_NSTEPS	Maximum no. of internal steps before t_{out}	500
MAX_ERRFAIL	Maximum no. of error test failures	7
MAX_NITERS	Maximum no. of nonlinear iterations	3
MAX_CONVFAIL	Maximum no. of convergence failures	10
HNIL_WARNS	Maximum no. of warnings for $t_n + h = t_n$	10
STAB_LIM	Flag to activate stability limit detection	0

Table 5.1: Keys for setting FCVODE optional inputs

Real optional inputs (FCVSETRIN)

	r	
Key	Optional input	Default value
INIT_STEP	Initial step size	estimated
MAX_STEP	Maximum absolute step size	∞
MIN_STEP	Minimum absolute step size	0.0
STOP_TIME	Value of t_{stop}	undefined
NLCONV_COEF	Coefficient in the nonlinear convergence test	0.1

where KEY is a quoted string indicating which optional input is set (see Table 5.1), IVAL is the integer input value to be used, RVAL is the real input value to be used, and IER is an integer return flag which is set to 0 on success and a negative value if a failure occurred. The integer IVAL should be declared in a manner consistent with C type long int.

The optional outputs from the CVODE solver are accessed not through individual functions, but rather through a pair of arrays, IOUT (integer type) of dimension at least 21, and ROUT (real type) of dimension at least 6. These arrays are owned (and allocated) by the user and are passed as arguments to FCVMALLOC. Table 5.2 lists the entries in these two arrays and specifies the optional variable as well as the CVODE function which is actually called to extract the optional output.

For more details on the optional inputs and outputs, see §4.5.7 and §4.5.9.

In addition to the optional inputs communicated through FCVSET* calls and the optional outputs extracted from IOUT and ROUT, the following user-callable routines are available:

To obtain the error weight array EWT, containing the multiplicative error weights used the WRMS norms, make the following call:

CALL FCVGETERRWEIGHTS (EWT, IER)

This computes the EWT array normally defined by Eq. (2.7). The array EWT, of length NEQ or NLOCAL, must already have been declared by the user. The error return flag IER is zero if successful, and negative if there was a memory error.

To obtain the estimated local errors, following a successful call to FCVSOLVE, make the following call:

CALL FCVGETESTLOCALERR (ELE, IER)

This computes the ELE array of estimated local errors as of the last step taken. The array ELE must already have been declared by the user. The error return flag IER is zero if successful, and negative if there was a memory error.

5.6 Usage of the FCVROOT interface to rootfinding

The FCVROOT interface package allows programs written in FORTRAN to use the rootfinding feature of the CVODE solver module. The user-callable functions in FCVROOT, with the corresponding CVODE functions, are as follows:

Table 5.2: Description of the FCVODE optional output arrays ${\tt IOUT}$ and ${\tt ROUT}$ Integer output array ${\tt IOUT}$

Index	Optional output	CVODE function
CVODE main solver		
1	LENRW	CVodeGetWorkSpace
2	LENIW	CVodeGetWorkSpace
3	NST	CVodeGetNumSteps
4	NFE	CVodeGetNumRhsEvals
5	NETF	CVodeGetNumErrTestFails

14	LENIWLS	CVDiagGetWorkSpace
15	LS_FLAG	CVDiagGetLastFlag
16	NFELS	CVDiagGetNumRhsEvals

Real output array \mathtt{ROUT}

Index	Optional output	CVODE function
1	HOU	CVodeGetActualInitStep
2	HU	CVodeGetLastStep
3	HCUR	CVodeGetCurrentStep
4	TCUR	CVodeGetCurrentTime
5	TOLSF	CVodeGetTolScaleFactor
6	UROUND	unit roundoff

- FCVROOTINIT interfaces to CVodeRootInit.
- FCVROOTINFO interfaces to CVodeGetRootInfo.
- FCVROOTFREE interfaces to CVodeRootFree.

Note that at this time, FCVROOT does not provide support to specify the direction of zero-crossing that is to be monitored. Instead, all roots are considered. However, the actual direction of zero-crossing is reported (through the sign of the non-zero elements in the array INFO returned by FCVROTINFO).

In order to use the rootfinding feature of CVODE, the following call must be made, after calling FCVMALLOC but prior to calling FCVODE, to allocate and initialize memory for the FCVROOT module:

```
CALL FCVROOTINIT (NRTFN, IER)
```

The arguments are as follows: NRTFN is the number of root functions. IER is a return completion flag; its values are 0 for success, -1 if the CVODE memory was NULL, and -11 if a memory allocation failed. To specify the functions whose roots are to be found, the user must define the following routine:

```
SUBROUTINE FCVROOTFN (T, Y, G, IPAR, RPAR, IER)
DIMENSION Y(*), G(*), IPAR(*), RPAR(*)
```

It must set the G array, of length NRTFN, with components $g_i(t, y)$, as a function of T = t and the array Y = y. The arrays IPAR (of integers) and RPAR (of reals) contain user data and are the same as those passed to FCVMALLOC. Set IER on 0 if successful, or on a non-zero value if an error occurred.

When making calls to FCVODE to solve the ODE system, the occurrence of a root is flagged by the return value IER = 2. In that case, if NRTFN > 1, the functions g_i which were found to have a root can be identified by making the following call:

```
CALL FCVROOTINFO (NRTFN, INFO, IER)
```

The arguments are as follows: NRTFN is the number of root functions. INFO is an integer array of length NRTFN with root information. IER is a return completion flag; its values are 0 for success, negative if there was a memory failure. The returned values of INFO(i) (i=1,...,NRTFN) are 0 or ± 1 , such that INFO(i) = +1 if g_i was found to have a root and g_i is increasing, INFO(i) = -1 if g_i was found to have a root and g_i is dereasing, and INFO(i) = 0 otherwise.

The total number of calls made to the root function FCVROOTFN, denoted NGE, can be obtained from IOUT(12). If the FCVODE/CVODE memory block is reinitialized to solve a different problem via a call to FCVREINIT, then the counter NGE is reset to zero.

To free the memory resources allocated by a prior call to FCVROOTINIT, make the following call:

CALL FCVROOTFREE

5.7 Usage of the FCVBP interface to CVBANDPRE

The FCVBP interface sub-module is a package of C functions which, as part of the FCVODE interface module, support the use of the CVODE solver with the serial NVECTOR_SERIAL module or multi-threaded NVECTOR_OPENMP or NVECTOR_PTHREADS, and the combination of the CVBANDPRE preconditioner module (see §4.7.1) with the CVSPILS interface and any of the Krylov iterative linear solvers.

The two user-callable functions in this package, with the corresponding CVODE function around which they wrap, are:

- FCVBPINIT interfaces to CVBandPrecInit.
- FCVBPOPT interfaces to CVBANDPRE optional output functions.

As with the rest of the FCVODE routines, the names of the user-supplied routines are mapped to actual values through a series of definitions in the header file fcvbp.h.

The following is a summary of the usage of this module. Steps that are unchanged from the main program described in §5.4 are grayed-out.

- 1. Right-hand side specification
- 2. NVECTOR module initialization

3. SUNLINSOL module initialization

Initialize one of the iterative SUNLINSOL modules, by calling one of FSUNPCGINIT, FSUNSPBCGSINIT, FSUNSPFGMRINIT, FSUNSPGMRINIT or FSUNSPTFQMRINIT.

- 4. Problem specification
- 5. Set optional inputs

6. Linear solver interface specification

First, initialize the CVSPILS iterative linear solver interface by calling FCVSPILSINIT.

Then, to initialize the CVBANDPRE preconditioner, make the following call:

```
CALL FCVBPINIT(NEQ, MU, ML, IER)
```

The arguments are as follows. NEQ is the problem size. MU and ML are the upper and lower half-bandwidths of the band matrix that is retained as an approximation of the Jacobian. IER is a return completion flag. A value of 0 indicates success, while a value of -1 indicates that a memory failure occurred.

Optionally, to specify that CVSPILS should use the supplied FCVJTIMES and FCVJTSETUP, make the call

```
CALL FCVSPILSSETJAC(FLAG, IER)
```

with FLAG $\neq 0$ (see step 8 in §5.4 for details).

- 7. Problem solution
- 8. Additional solution output

9. CVBANDPRE Optional outputs

Optional outputs specific to the CVSPILS solver interface are listed in Table 5.2. To obtain the optional outputs associated with the CVBANDPRE module, make the following call:

```
CALL FCVBPOPT(LENRWBP, LENIWBP, NFEBP)
```

The arguments should be consistent with C type long int. Their returned values are as follows: LENRWBP is the length of real preconditioner work space, in realtype words. LENIWBP is the length of integer preconditioner work space, in integer words. NFEBP is the number of f(t, y) evaluations (calls to FCVFUN) for difference-quotient banded Jacobian approximations.

10. Memory deallocation

(The memory allocated for the FCVBP module is deallocated automatically by FCVFREE.)

5.8 Usage of the FCVBBD interface to CVBBDPRE

The FCVBBD interface sub-module is a package of C functions which, as part of the FCVODE interface module, support the use of the CVODE solver with the parallel NVECTOR_PARALLEL module, and the combination of the CVBBDPRE preconditioner module (see §4.7.2) with any of the Krylov iterative linear solvers.

The user-callable functions in this package, with the corresponding CVODE and CVBBDPRE functions, are as follows:

- FCVBBDINIT interfaces to CVBBDPrecInit.
- FCVBBDREINIT interfaces to CVBBDPrecReInit.
- FCVBBDOPT interfaces to CVBBDPRE optional output functions.

In addition to the FORTRAN right-hand side function FCVFUN, the user-supplied functions used by this package, are listed below, each with the corresponding interface function which calls it (and its type within CVBBDPRE or CVODE):

FCVBBD routine	CVODE function	CVODE type of
(Fortran, user-supplied)	(C, interface)	interface function
FCVLOCFN	FCVgloc	CVLocalFn
FCVCOMMF	FCVcfn	CVCommFn
FCVJTIMES	FCVJtimes	CVSpilsJacTimesVecFn
FCVJTSETUP	FCVJTSetup	CVSpilsJacTimesSetupFn

As with the rest of the FCVODE routines, the names of all user-supplied routines here are fixed, in order to maximize portability for the resulting mixed-language program. Additionally, based on flags discussed above in §5.3, the names of the user-supplied routines are mapped to actual values through a series of definitions in the header file fcvbbd.h.

The following is a summary of the usage of this module. Steps that are unchanged from the main program described in $\S 5.4$ are grayed-out.

- 1. Right-hand side specification
- 2. NVECTOR module initialization
- 3. SUNLINSOL module initialization

Initialize one of the iterative SUNLINSOL modules, by calling one of FSUNPCGINIT, FSUNSPBCGSINIT, FSUNSPFGMRINIT, FSUNSPGMRINIT or FSUNSPTFQMRINIT.

- 4. Problem specification
- 5. Set optional inputs

6. Linear solver interface specification

First, initialize the CVSPILS iterative linear solver interface by calling FCVSPILSINIT.

Then, to initialize the CVBBDPRE preconditioner, make the following call:

```
CALL FCVBBDINIT(NLOCAL, MUDQ, MLDQ, MU, ML, DQRELY, IER)
```

The arguments are as follows. NLOCAL is the local size of vectors on this processor. MUDQ and MLDQ are the upper and lower half-bandwidths to be used in the computation of the local Jacobian blocks by difference quotients. These may be smaller than the true half-bandwidths of the Jacobian of the local block of g, when smaller values may provide greater efficiency. MU and ML are the upper and lower half-bandwidths of the band matrix that is retained as an approximation of the local

Jacobian block. These may be smaller than MUDQ and MLDQ. DQRELY is the relative increment factor in y for difference quotients (optional). A value of 0.0 indicates the default, $\sqrt{\text{unit roundoff}}$. IER is a return completion flag. A value of 0 indicates success, while a value of -1 indicates that a memory failure occurred or that an input had an illegal value.

Optionally, to specify that SPGMR, SPBCGS, or SPTFQMR should use the supplied FCVJTIMES, make the call

```
CALL FCVSPILSSETJAC(FLAG, IER)
```

with FLAG $\neq 0$ (see step 8 in §5.4 for details).

- 7. Problem solution
- 8. Additional solution output

9. CVBBDPRE **Optional outputs**

Optional outputs specific to the CVSPILS solver interface are listed in Table 5.2. To obtain the optional outputs associated with the CVBBDPRE module, make the following call:

```
CALL FCVBBDOPT(LENRWBBD, LENIWBBD, NGEBBD)
```

The arguments should be consistent with C type long int. Their returned values are as follows: LENRWBBD is the length of real preconditioner work space, in realtype words. LENIWBBD is the length of integer preconditioner work space, in integer words. These sizes are local to the current processor. NGEBBD is the number of g(t, y) evaluations (calls to FCVLOCFN) so far.

10. Problem reinitialization

If a sequence of problems of the same size is being solved using the same linear solver in combination with the CVBBDPRE preconditioner, then the CVODE package can be re-initialized for the second and subsequent problems by calling FCVREINIT, following which a call to FCVBBDINIT may or may not be needed. If the input arguments are the same, no FCVBBDINIT call is needed. If there is a change in input arguments other than MU or ML, then the user program should make the call

```
CALL FCVBBDREINIT(NLOCAL, MUDQ, MLDQ, DQRELY, IER)
```

This reinitializes the CVBBDPRE preconditioner, but without reallocating its memory. The arguments of the FCVBBDREINIT routine have the same names and meanings as those of FCVBBDINIT. If the value of MU or ML is being changed, then a call to FCVBBDINIT must be made. Finally, if there is a change in any of the linear solver inputs, then a call to one of FSUNPCGINIT, FSUNSPBCGSINIT, FSUNSPFGMRINIT or FSUNSPTFQMRINIT, followed by a call to FCVSPILSINIT must also be made; in this case the linear solver memory is reallocated.

11. Memory deallocation

(The memory allocated for the FCVBBD module is deallocated automatically by FCVFREE.)

12. User-supplied routines

The following two routines must be supplied for use with the CVBBDPRE module:

```
SUBROUTINE FCVGLOCFN (NLOC, T, YLOC, GLOC, IPAR, RPAR, IER)
DIMENSION YLOC(*), GLOC(*), IPAR(*), RPAR(*)
```

This routine is to evaluate the function g(t, y) approximating f (possibly identical to f), in terms of T = t, and the array YLOC (of length NLOC), which is the sub-vector of y local to this processor.

The resulting (local) sub-vector is to be stored in the array GLOC. The arrays IPAR (of integers) and RPAR (of reals) contain user data and are the same as those passed to FCVMALLOC. IER is an error return flag which should be set to 0 if successful, a positive value if a recoverable error occurred (in which case CVODE will attempt to correct), or a negative value if FCVGLOCFN failed unrecoverably (in which case the integration is halted).

SUBROUTINE FCVCOMMFN (NLOC, T, YLOC, IPAR, RPAR, IER) DIMENSION YLOC(*), IPAR(*), RPAR(*)

This routine is to perform the inter-processor communication necessary for the FCVGLOCFN routine. Each call to FCVCOMMFN is preceded by a call to the right-hand side routine FCVFUN with the same arguments T and YLOC. The arrays IPAR (of integers) and RPAR (of reals) contain user data and are the same as those passed to FCVMALLOC. IER is an error return flag (currently not used; set IER=0). Thus FCVCOMMFN can omit any communications done by FCVFUN if relevant to the evaluation of GLOC. IER is an error return flag which should be set to 0 if successful, a positive value if a recoverable error occurred (in which case CVODE will attempt to correct), or a negative value if FCVCOMMFN failed unrecoverably (in which case the integration is halted).

The subroutine FCVCOMMFN must be supplied even if it is not needed and must return IER=0.

Optionally, the user can supply routines FCVJTIMES and FCVJTSETUP for the evaluation of Jacobian-vector products, as described above in step 8 in §5.4.

Chapter 6

Description of the NVECTOR module

The SUNDIALS solvers are written in a data-independent manner. They all operate on generic vectors (of type N_Vector) through a set of operations defined by the particular NVECTOR implementation. Users can provide their own specific implementation of the NVECTOR module, or use one of the implementations provided with SUNDIALS. The generic operations are described below and the implementations provided with SUNDIALS are described in the following sections.

The generic N_Vector type is a pointer to a structure that has an implementation-dependent content field containing the description and actual data of the vector, and an ops field pointing to a structure with generic vector operations. The type N_Vector is defined as

```
typedef struct _generic_N_Vector *N_Vector;
struct _generic_N_Vector {
    void *content;
    struct _generic_N_Vector_Ops *ops;
};
```

The _generic_N_Vector_Ops structure is essentially a list of pointers to the various actual vector operations, and is defined as

```
struct _generic_N_Vector_Ops {
  N_Vector_ID (*nvgetvectorid)(N_Vector);
  N_Vector
              (*nvclone)(N_Vector);
  N_Vector
              (*nvcloneempty)(N_Vector);
  void
              (*nvdestroy)(N_Vector);
              (*nvspace)(N_Vector, sunindextype *, sunindextype *);
  void
              (*nvgetarraypointer)(N_Vector);
  realtype*
              (*nvsetarraypointer)(realtype *, N_Vector);
  void
  void
              (*nvlinearsum)(realtype, N_Vector, realtype, N_Vector, N_Vector);
              (*nvconst)(realtype, N_Vector);
  void
  void
              (*nvprod)(N_Vector, N_Vector, N_Vector);
              (*nvdiv)(N_Vector, N_Vector, N_Vector);
  void
              (*nvscale)(realtype, N_Vector, N_Vector);
  void
  void
              (*nvabs)(N_Vector, N_Vector);
              (*nvinv)(N_Vector, N_Vector);
  void
  void
              (*nvaddconst)(N_Vector, realtype, N_Vector);
  realtype
              (*nvdotprod)(N_Vector, N_Vector);
  realtype
              (*nvmaxnorm)(N_Vector);
  realtype
              (*nvwrmsnorm)(N_Vector, N_Vector);
```

```
(*nvwrmsnormmask)(N_Vector, N_Vector, N_Vector);
  realtype
  realtype
              (*nvmin)(N_Vector);
              (*nvwl2norm)(N_Vector, N_Vector);
  realtype
  realtype
              (*nvl1norm)(N_Vector);
  void
              (*nvcompare)(realtype, N_Vector, N_Vector);
  booleantype (*nvinvtest)(N_Vector, N_Vector);
  booleantype (*nvconstrmask)(N_Vector, N_Vector, N_Vector);
              (*nvminquotient)(N_Vector, N_Vector);
  realtype
              (*nvlinearcombination)(int, realtype*, N_Vector*, N_Vector);
  int
  int
              (*nvscaleaddmulti)(int, realtype*, N_Vector, N_Vector*, N_Vector*);
              (*nvdotprodmulti)(int, N_Vector, N_Vector*, realtype*);
  int
              (*nvlinearsumvectorarray)(int, realtype, N_Vector*, realtype,
  int
                                         N_Vector*, N_Vector*);
  int
              (*nvscalevectorarray)(int, realtype*, N_Vector*, N_Vector*);
  int
              (*nvconstvectorarray)(int, realtype, N_Vector*);
              (*nvwrmsnomrvectorarray)(int, N_Vector*, N_Vector*, realtype*);
  int
  int
              (*nvwrmsnomrmaskvectorarray)(int, N_Vector*, N_Vector*, N_Vector,
                                            realtype*);
  int
              (*nvscaleaddmultivectorarray)(int, int, realtype*, N_Vector*,
                                             N_Vector**, N_Vector**);
              (*nvlinearcombinationvectorarray)(int, int, realtype*, N_Vector**,
  int
                                                 N Vector*):
};
```

These routines are nothing but wrappers for the vector operations defined by a particular NVECTOR implementation, which are accessed through the *ops* field of the N_Vector structure. To illustrate this point we show below the implementation of a typical vector operation from the generic NVECTOR module, namely N_VScale, which performs the scaling of a vector x by a scalar c:

```
void N_VScale(realtype c, N_Vector x, N_Vector z)
{
   z->ops->nvscale(c, x, z);
}
```

Table 6.2 contains a complete list of all standard vector operations defined by the generic NVEC-TOR module. Tables 6.3 and 6.4 list *optional* fused and vector array operations respectively. These operations are intended to increase data reuse, reduce parallel communication on distributed memory systems, and lower the number of kernel launches on systems with accelerators. If a particular NVECTOR implementation defines one of the fused or vector array operations as NULL, the NVECTOR interface will call one of the standard vector operations as necessary.

Finally, note that the generic NVECTOR module defines the functions N_VCloneVectorArray and N_VCloneVectorArrayEmpty. Both functions create (by cloning) an array of count variables of type N_Vector, each of the same type as an existing N_Vector. Their prototypes are

```
N_Vector *N_VCloneVectorArray(int count, N_Vector w);
N_Vector *N_VCloneVectorArrayEmpty(int count, N_Vector w);
```

and their definitions are based on the implementation-specific N_VClone and $N_VCloneEmpty$ operations, respectively.

An array of variables of type N_Vector can be destroyed by calling $N_VDestroyVectorArray$, whose prototype is

```
void N_VDestroyVectorArray(N_Vector *vs, int count);
```

and whose definition is based on the implementation-specific N_VDestroy operation.

A particular implementation of the NVECTOR module must:

Vector ID	Vector type	ID Value
SUNDIALS_NVEC_SERIAL	Serial	0
SUNDIALS_NVEC_PARALLEL	Distributed memory parallel (MPI)	1
SUNDIALS_NVEC_OPENMP	OpenMP shared memory parallel	2
SUNDIALS_NVEC_PTHREADS	PThreads shared memory parallel	3
SUNDIALS_NVEC_PARHYP	hypre ParHyp parallel vector	4
SUNDIALS_NVEC_PETSC	PETSc parallel vector	5
SUNDIALS NVEC CUSTOM	User-provided custom vector	6

Table 6.1: Vector Identifications associated with vector kernels supplied with SUNDIALS.

- Specify the *content* field of N_Vector.
- Define and implement the vector operations. Note that the names of these routines should be unique to that implementation in order to permit using more than one NVECTOR module (each with different N_Vector internal data representations) in the same code.
- Define and implement user-callable constructor and destructor routines to create and free an N_Vector with the new *content* field and with *ops* pointing to the new vector operations.
- Optionally, define and implement additional user-callable routines acting on the newly defined N_Vector (e.g., a routine to print the content for debugging purposes).
- Optionally, provide accessor macros as needed for that particular implementation to be used to access different parts in the *content* field of the newly defined N_Vector.

Each NVECTOR implementation included in SUNDIALS has a unique identifier specified in enumeration and shown in Table 6.1. It is recommended that a user-supplied NVECTOR implementation use the SUNDIALS_NVEC_CUSTOM identifier.

Table 6.2: Description of the NVECTOR operations

Name	Usage and Description
N_VGetVectorID	<pre>id = N_VGetVectorID(w); Returns the vector type identifier for the vector w. It is used to determine the vector implementation type (e.g. serial, parallel,) from the abstract N_Vector interface. Returned values are given in Table 6.1.</pre>
N_VClone	<pre>v = N_VClone(w); Creates a new N_Vector of the same type as an existing vector w and sets the ops field. It does not copy the vector, but rather allocates storage for the new vector.</pre>
	continued on next page

continued from last page	continued from last page	
Name	Usage and Description	
N_VCloneEmpty	v = N_VCloneEmpty(w); Creates a new N_Vector of the same type as an existing vector w and sets the ops field. It does not allocate storage for data.	
N_VDestroy	N_VDestroy(v); Destroys the N_Vector v and frees memory allocated for its internal data.	
N_VSpace	N_VSpace(nvSpec, &lrw, &liw); Returns storage requirements for one N_Vector. lrw contains the number of realtype words and liw contains the number of integer words. This function is advisory only, for use in determining a user's total space requirements; it could be a dummy function in a user-supplied NVECTOR module if that information is not of interest.	
N_VGetArrayPointer	vdata = N_VGetArrayPointer(v); Returns a pointer to a realtype array from the N_Vector v. Note that this assumes that the internal data in N_Vector is a contiguous array of realtype. This routine is only used in the solver-specific interfaces to the dense and banded (serial) linear solvers, the sparse linear solvers (serial and threaded), and in the interfaces to the banded (serial) and band-block- diagonal (parallel) preconditioner modules provided with SUNDIALS.	
N_VSetArrayPointer	N_VSetArrayPointer(vdata, v); Overwrites the data in an N_Vector with a given array of realtype. Note that this assumes that the internal data in N_Vector is a contiguous array of realtype. This routine is only used in the interfaces to the dense (serial) linear solver, hence need not exist in a user-supplied NVECTOR module for a parallel environment.	
N_VLinearSum	N_VLinearSum(a, x, b, y, z); Performs the operation $z = ax + by$, where a and b are realtype scalars and x and y are of type N_Vector: $z_i = ax_i + by_i$, $i = 0,, n-1$.	
N_VConst	N_VConst(c, z); Sets all components of the N_Vector z to realtype c: $z_i=c, i=0,\ldots,n-1.$	
N_VProd	N_VProd(x, y, z); Sets the N_Vector z to be the component-wise product of the N_Vector inputs x and y: $z_i = x_i y_i$, $i = 0, \ldots, n-1$.	
	continued on next page	

continued from last pa	ge		
Name	Usage and Description		
N_VDiv	N_VDiv(x, y, z); Sets the N_Vector z to be the component-wise ratio of the N_Vector inputs x and y: $z_i = x_i/y_i$, $i = 0,, n-1$. The y_i may not be tested for 0 values. It should only be called with a y that is guaranteed to have all nonzero components.		
N_VScale	N_VScale(c, x, z); Scales the N_Vector x by the realtype scalar c and returns the result in z: $z_i = cx_i$, $i = 0,, n-1$.		
N_VAbs	N_VAbs(x, z); Sets the components of the N_Vector z to be the absolute values of the components of the N_Vector x: $y_i = x_i , i = 0, \ldots, n-1$.		
N_VInv	N_VInv(x, z); Sets the components of the N_Vector z to be the inverses of the components of the N_Vector x: $z_i = 1.0/x_i$, $i = 0, \ldots, n-1$. This routine may not check for division by 0. It should be called only with an x which is guaranteed to have all nonzero components.		
N_VAddConst	N_VAddConst(x, b, z); Adds the realtype scalar b to all components of x and returns the result in the N_Vector z: $z_i = x_i + b, i = 0, \ldots, n-1$.		
$N_VDotProd$	d = N_VDotProd(x, y); Returns the value of the ordinary dot product of x and y: $d = \sum_{i=0}^{n-1} x_i y_i$.		
N_VMaxNorm	m = N_VMaxNorm(x); Returns the maximum norm of the N_Vector x: $m = \max_i x_i $.		
N_VWrmsNorm	m = N_VWrmsNorm(x, w) Returns the weighted root-mean-square norm of the N_Vector x with		
	realtype weight vector w: $m = \sqrt{\left(\sum_{i=0}^{n-1} (x_i w_i)^2\right)/n}$.		
N_VWrmsNormMask	m = N_VWrmsNormMask(x, w, id); Returns the weighted root mean square norm of the N_Vector x with realtype weight vector w built using only the elements of x corresponding to positive elements of the N_Vector id:		
	$m = \sqrt{\left(\sum_{i=0}^{n-1} (x_i w_i H(id_i))^2\right)/n}, \text{ where } H(\alpha) = \begin{cases} 1 & \alpha > 0\\ 0 & \alpha \le 0 \end{cases}$		
	continued on next page		

continued from last pa	age
Name	Usage and Description
N_VMin	$m = N_VMin(x);$ Returns the smallest element of the $N_Vector x$: $m = \min_i x_i$.
N_VWL2Norm	m = N_VWL2Norm(x, w); Returns the weighted Euclidean ℓ_2 norm of the N_Vector x with realtype weight vector w: $m = \sqrt{\sum_{i=0}^{n-1} (x_i w_i)^2}$.
N_VL1Norm	m = N_VL1Norm(x); Returns the ℓ_1 norm of the N_Vector x: $m = \sum_{i=0}^{n-1} x_i $.
N_VCompare	N_VCompare(c, x, z); Compares the components of the N_Vector x to the realtype scalar c and returns an N_Vector z such that: $z_i = 1.0$ if $ x_i \ge c$ and $z_i = 0.0$ otherwise.
N_VInvTest	t = N_VInvTest(x, z); Sets the components of the N_Vector z to be the inverses of the components of the N_Vector x, with prior testing for zero values: $z_i = 1.0/x_i$, $i = 0, \ldots, n-1$. This routine returns a boolean assigned to SUNTRUE if all components of x are nonzero (successful inversion) and returns SUNFALSE otherwise.
N_VConstrMask	t = N_VConstrMask(c, x, m); Performs the following constraint tests: $x_i > 0$ if $c_i = 2$, $x_i \geq 0$ if $c_i = 1$, $x_i \leq 0$ if $c_i = -1$, $x_i < 0$ if $c_i = -2$. There is no constraint on x_i if $c_i = 0$. This routine returns a boolean assigned to SUNFALSE if any element failed the constraint test and assigned to SUNTRUE if all passed. It also sets a mask vector m, with elements equal to 1.0 where the constraint test failed, and 0.0 where the test passed. This routine is used only for constraint checking.
N_VMinQuotient	minq = N_VMinQuotient(num, denom); This routine returns the minimum of the quotients obtained by term-wise dividing num _i by denom _i . A zero element in denom will be skipped. If no such quotients are found, then the large value BIG_REAL (defined in the header file sundials_types.h) is returned.

Table 6.3: Description of the NVECTOR fused operations

Name	Usage and Description
N_VLinearCombination	ier = N_VLinearCombination(nv, c, X, z); This routine computes the linear combination of nv vectors with n elements: $z_i = \sum_{j=1}^{nv} c_j x_{j,i}, i=1,\ldots,n,$
	where c is an array of nv scalars (type realtype*), X is an array of n vectors (type N_Vector*), and z is the output vector (type N_Vector). If the output vector z is one of the vectors in X , then it $must$ be the first vector in the vector array. The operation returns 0 for success and a non-zero value otherwise.
N_VScaleAddMulti	<pre>ier = N_VScaleAddMulti(nv, c, x, Y, Z); This routine scales and adds one vector to nv vectors with n elements:</pre>
	$z_{j,i} = c_j x_i + y_{j,i}, j = 1, \dots, nv i = 1, \dots, n,$
	where c is an array of nv scalars (type realtype*), x is the vector (type N_Vector) to be scaled and added to each vector in the vector array of nv vectors Y (type N_Vector*), and Z (type N_Vector*) is a vector array of nv output vectors. The operation returns 0 for success and a non-zero value otherwise.
N_VDotProdMulti	<pre>ier = N_VDotProdMulti(nv, x, Y, d); This routine computes the dot product of a vector with nv other vectors:</pre>
	$d_j = \sum_{i=1}^{n} x_i y_{j,i}, j = 1, \dots, nv,$
	where d (type realtype*) is an array of nv scalars containing the dot products of the vector x (type N_Vector) with each of the nv vectors in the vector array Y (type N_Vector*). The operation returns 0 for success and a non-zero value otherwise.
	continued on next page

continued from last page	
Name	Usage and Description

Usage and Description
<pre>ier = N_VLinearSumVectorArray(nv, a, X, b, Y, Z); This routine comuptes the linear sum of two vector arrays containing nv vectors of n elements:</pre>
$z_{j,i} = ax_{j,i} + by_{j,i}, i = 1, \dots, n j = 1, \dots, nv,$
where a and b are realtype scalars and X , Y , and Z are arrays of nv vectors (type N_Vector*). The operation returns 0 for success and a non-zero value otherwise.
ier = $N_VScaleVectorArray(nv, c, X, Z)$; This routine scales each vector of n elements in a vector array of nv vectors by a potentially different constant:
$z_{j,i}=c_jx_{j,i}, i=1,\ldots,n j=1,\ldots,nv,$
where c is an array of nv scalars (type realtype*) and X and Z are arrays of nv vectors (type N_Vector*). The operation returns 0 for success and a non-zero value otherwise.
ier = N_VConstVectorArray(nv, c, X); This routine sets each element in a vector of n elements in a vector array of nv vectors to the same value:
$z_{j,i}=c, i=1,\ldots,n j=1,\ldots,nv,$
where c is a realtype scalar and X is an array of nv vectors (type N_Vector*). The operation returns 0 for success and a non-zero value otherwise.

continued from last page	
Name	Usage and Description
N_VWrmsNormVectorArray	ier = N_VWrmsNormVectorArray(nv, X, W, m); This routine computes the weighted root mean square norm of nv vectors with n elements:
	$m_j = \left(\frac{1}{n}\sum_{i=1}^n (x_{j,i}w_{j,i})^2\right)^{1/2}, j = 1, \dots, nvec,$
	where m (type realtype*) contains the nv norms of the vectors in the vector array X (type N_Vector*) with corresponding weight vectors W (type N_Vector*). The operation returns 0 for success and a non-zero value otherwise.
N_VWrmsNormMaskVectorArray	<pre>ier = N_VWrmsNormMaskVectorArray(nv, X, W, id, m); This routine computes the masked weighted root mean square norm of nv vectors with n elements:</pre>
	$m_j = \left(\frac{1}{n}\sum_{i=1}^n (x_{j,i}w_{j,i}H(id_i))^2\right)^{1/2}, j = 1, \dots, nvec,$
	$H(id_i)=1$ for $id_i>0$ and is zero otherwise, m (type realtype*) contains the nv norms of the vectors in the vector array X (type N_Vector*) with corresponding weight vectors W (type N_Vector*) and mask vector id (type N_Vector). The operation returns 0 for success and a non-zero value otherwise.
${ t N_VScaleAddMultiVectorArray}$	<pre>ier = N_VScaleAddMultiVectorArray(nv, ns, c, X, YY, ZZ); This routine scales and adds a vector in a vector array of nv vectors to the corresponding vector in ns vector arrays:</pre>
	$z_{j,i} = \sum_{k=1}^{ns} c_k x_{k,j,i}, i = 1, \dots, n j = 1, \dots, nv,$
	where c is an array of ns scalars (type realtype*), X is a vector array of nv vectors (type idN_Vector*) to be scaled and added to the corresponding vector in each of the ns vector arrays in the array of vector arrays YY (type N_Vector**) and stored in the output array of vector arrays ZZ (type N_Vector**). The operation returns 0 for success and a non-zero value otherwise.
	continued on next page

continued from last page	
Name	Usage and Description
N_VLinearCombinationVectorArray	ier = N_VLinearCombinationVectorArray(nv, ns, c, XX, Z); This routine computes the linear combination of ns vector arrays containing nv vectors with n elements: $z_{j,i} = \sum_{k=1}^{ns} c_k x_{k,j,i}, i=1,\ldots,n j=1,\ldots,nv,$ where c is an array of ns scalars (type realtype*), XX (type N_Vector**) is an array of ns vector arrays each containing nv vectors to be summed into the output vector array of nv vectors ZZ (type N_Vector*). If the output vector array ZZ is one of the vector arrays in XX , then it $must$ be the first vector array in XX . The operation returns 0 for success and a non-zero value otherwise.

6.1 The NVECTOR_SERIAL implementation

The serial implementation of the NVECTOR module provided with SUNDIALS, NVECTOR_SERIAL, defines the *content* field of N_Vector to be a structure containing the length of the vector, a pointer to the beginning of a contiguous data array, and a boolean flag own_data which specifies the ownership of data

```
struct _N_VectorContent_Serial {
   sunindextype length;
   booleantype own_data;
   realtype *data;
};
```

The header file to include when using this module is $nvector_serial.h$. The installed module library to link to is $libsundials_nvecserial.lib$ where .lib is typically .so for shared libraries and .a for static libraries.

The following macros are provided to access the content of an NVECTOR_SERIAL vector. The suffix _S in the names denotes the serial version.

• NV_CONTENT_S

This routine gives access to the contents of the serial vector N_Vector.

The assignment $v_{cont} = NV_{content_S(v)}$ sets v_{cont} to be a pointer to the serial $N_{content}$ content structure.

Implementation:

```
#define NV_CONTENT_S(v) ( (N_VectorContent_Serial)(v->content) )
```

• NV_OWN_DATA_S, NV_DATA_S, NV_LENGTH_S

These macros give individual access to the parts of the content of a serial N_Vector.

The assignment $v_{data} = NV_DATA_S(v)$ sets v_{data} to be a pointer to the first component of the data for the $N_Vector v$. The assignment $NV_DATA_S(v) = v_{data}$ sets the component array of v to be v_{data} by storing the pointer v_{data} .

The assignment $v_len = NV_LENGTH_S(v)$ sets v_len to be the length of v. On the other hand, the call $NV_LENGTH_S(v) = len_v$ sets the length of v to be len_v .

Implementation:

```
#define NV_OWN_DATA_S(v) ( NV_CONTENT_S(v)->own_data )
#define NV_DATA_S(v) ( NV_CONTENT_S(v)->data )
#define NV_LENGTH_S(v) ( NV_CONTENT_S(v)->length )
```

• NV_Ith_S

This macro gives access to the individual components of the data array of an N_Vector.

The assignment $r = NV_{i,i}$ sets r to be the value of the i-th component of v. The assignment $NV_{i,i} = r$ sets the value of the i-th component of v to be r.

Here i ranges from 0 to n-1 for a vector of length n.

Implementation:

```
#define NV_Ith_S(v,i) ( NV_DATA_S(v)[i] )
```

The NVECTOR_SERIAL module defines serial implementations of all vector operations listed in Tables 6.2, 6.3, and 6.4. Their names are obtained from those in Tables 6.2, 6.3, and 6.4. by appending the suffix _Serial (e.g. N_VDestroy_Serial). The module NVECTOR_SERIAL provides the following additional user-callable routines:

• N_VNew_Serial

This function creates and allocates memory for a serial N_Vector. Its only argument is the vector length.

N_Vector N_VNew_Serial(sunindextype vec_length);

• N_VNewEmpty_Serial

This function creates a new serial N_Vector with an empty (NULL) data array.

N_Vector N_VNewEmpty_Serial(sunindextype vec_length);

• N_VMake_Serial

This function creates and allocates memory for a serial vector with user-provided data array.

(This function does *not* allocate memory for v_data itself.)

N_Vector N_VMake_Serial(sunindextype vec_length, realtype *v_data);

• N_VCloneVectorArray_Serial

This function creates (by cloning) an array of count serial vectors.

N_Vector *N_VCloneVectorArray_Serial(int count, N_Vector w);

N_VCloneVectorArrayEmpty_Serial

This function creates (by cloning) an array of count serial vectors, each with an empty (NULL) data array.

N_Vector *N_VCloneVectorArrayEmpty_Serial(int count, N_Vector w);

$\bullet \ {\tt N_VDestroyVectorArray_Serial}$

This function frees memory allocated for the array of count variables of type N_Vector created with N_VCloneVectorArray_Serial or with N_VCloneVectorArrayEmpty_Serial.

```
void N_VDestroyVectorArray_Serial(N_Vector *vs, int count);
```

• N_VGetLength_Serial

This function returns the number of vector elements.

```
sunindextype N_VGetLength_Serial(N_Vector v);
```

• N_VPrint_Serial

```
This function prints the content of a serial vector to stdout.
```

```
void N_VPrint_Serial(N_Vector v);
```

• N_VPrintFile_Serial

This function prints the content of a serial vector to outfile.

```
void N_VPrintFile_Serial(N_Vector v, FILE *outfile);
```

Notes

• When looping over the components of an N_Vector v, it is more efficient to first obtain the component array via v_data = NV_DATA_S(v) and then access v_data[i] within the loop than it is to use NV_Ith_S(v,i) within the loop.

• N_VNewEmpty_Serial, N_VMake_Serial, and N_VCloneVectorArrayEmpty_Serial set the field $own_data = SUNFALSE$. N_VDestroy_Serial and N_VDestroyVectorArray_Serial will not attempt to free the pointer data for any N_Vector with own_data set to SUNFALSE. In such a case, it is the user's responsibility to deallocate the data pointer.

• To maximize efficiency, vector operations in the NVECTOR_SERIAL implementation that have more than one N_Vector argument do not check for consistent internal representation of these vectors. It is the user's responsibility to ensure that such routines are called with N_Vector arguments that were all created with the same internal representations.

For solvers that include a Fortran interface module, the NVECTOR_SERIAL module also includes a Fortran-callable function FNVINITS(code, NEQ, IER), to initialize this NVECTOR_SERIAL module. Here code is an input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); NEQ is the problem size (declared so as to match C type long int); and IER is an error return flag equal 0 for success and -1 for failure.

6.2 The NVECTOR_PARALLEL implementation

The NVECTOR_PARALLEL implementation of the NVECTOR module provided with SUNDIALS is based on MPI. It defines the *content* field of N_Vector to be a structure containing the global and local lengths of the vector, a pointer to the beginning of a contiguous local data array, an MPI communicator, and a boolean flag own_data indicating ownership of the data array data.

```
struct _N_VectorContent_Parallel {
   sunindextype local_length;
   sunindextype global_length;
   booleantype own_data;
   realtype *data;
   MPI_Comm comm;
};
```

The header file to include when using this module is nvector_parallel.h. The installed module library to link to is libsundials_nvecparallel.lib where .lib is typically .so for shared libraries and .a for static libraries.

The following macros are provided to access the content of a NVECTOR_PARALLEL vector. The suffix _P in the names denotes the distributed memory parallel version.

• NV_CONTENT_P

This macro gives access to the contents of the parallel vector N_Vector.

The assignment v_cont = NV_CONTENT_P(v) sets v_cont to be a pointer to the N_Vector content structure of type struct _N_VectorContent_Parallel.

Implementation:

```
#define NV_CONTENT_P(v) ( (N_VectorContent_Parallel)(v->content) )
```

• NV_OWN_DATA_P, NV_DATA_P, NV_LOCLENGTH_P, NV_GLOBLENGTH_P

These macros give individual access to the parts of the content of a parallel N_Vector.

The assignment $v_{data} = NV_DATA_P(v)$ sets v_{data} to be a pointer to the first component of the local data for the $N_Vector\ v$. The assignment $NV_DATA_P(v) = v_{data}$ sets the component array of v to be v_{data} by storing the pointer v_{data} .

The assignment v_llen = NV_LOCLENGTH_P(v) sets v_llen to be the length of the local part of v. The call NV_LENGTH_P(v) = $llen_v$ sets the local length of v to be $llen_v$.

The assignment $v_glen = NV_GLOBLENGTH_P(v)$ sets v_glen to be the global length of the vector v. The call $NV_GLOBLENGTH_P(v) = glen_v$ sets the global length of v to be $glen_v$.

Implementation:

```
#define NV_OWN_DATA_P(v) ( NV_CONTENT_P(v)->own_data )
#define NV_DATA_P(v) ( NV_CONTENT_P(v)->data )
#define NV_LOCLENGTH_P(v) ( NV_CONTENT_P(v)->local_length )
#define NV_GLOBLENGTH_P(v) ( NV_CONTENT_P(v)->global_length )
```

NV_COMM_P

This macro provides access to the MPI communicator used by the NVECTOR_PARALLEL vectors. Implementation:

```
#define NV_COMM_P(v) ( NV_CONTENT_P(v)->comm )
```

• NV Ith P

This macro gives access to the individual components of the local data array of an N_Vector.

The assignment $r = NV_i(v,i)$ sets r to be the value of the i-th component of the local part of v. The assignment $NV_i(v,i) = r$ sets the value of the i-th component of the local part of v to be r.

Here i ranges from 0 to n-1, where n is the local length.

Implementation:

```
#define NV_Ith_P(v,i) ( NV_DATA_P(v)[i] )
```

The NVECTOR_PARALLEL module defines parallel implementations of all vector operations listed in Tables 6.2, 6.3, and 6.4. Their names are obtained from those in Tables 6.2, 6.3, and 6.4 by appending the suffix _Parallel (e.g. N_VDestroy_Parallel). The module NVECTOR_PARALLEL provides the following additional user-callable routines:

• N_VNew_Parallel

This function creates and allocates memory for a parallel vector.

• N_VNewEmpty_Parallel

This function creates a new parallel N_Vector with an empty (NULL) data array.

• N_VMake_Parallel

This function creates and allocates memory for a parallel vector with user-provided data array. (This function does *not* allocate memory for v_data itself.)

• N_VCloneVectorArray_Parallel

This function creates (by cloning) an array of count parallel vectors.

```
N_Vector *N_VCloneVectorArray_Parallel(int count, N_Vector w);
```

• N_VCloneVectorArrayEmpty_Parallel

This function creates (by cloning) an array of count parallel vectors, each with an empty (NULL) data array.

```
N_Vector *N_VCloneVectorArrayEmpty_Parallel(int count, N_Vector w);
```

• N_VDestroyVectorArray_Parallel

This function frees memory allocated for the array of count variables of type N_Vector created with N_VCloneVectorArray_Parallel or with N_VCloneVectorArrayEmpty_Parallel.

```
void N_VDestroyVectorArray_Parallel(N_Vector *vs, int count);
```

• N_VGetLength_Parallel

This function returns the number of vector elements (global vector length). sunindextype N_VGetLength_Parallel(N_Vector v);

• N_VGetLocalLength_Parallel

This function returns the local vector length.
sunindextype N_VGetLocalLength_Parallel(N_Vector v);

• N_VPrint_Parallel

This function prints the local content of a parallel vector to ${\tt stdout}.$

```
void N_VPrint_Parallel(N_Vector v);
```

• N_VPrintFile_Parallel

This function prints the local content of a parallel vector to outfile. void N_VPrintFile_Parallel(N_Vector v, FILE *outfile);

Notes

• When looping over the components of an N_Vector v, it is more efficient to first obtain the local component array via v_data = NV_DATA_P(v) and then access v_data[i] within the loop than it is to use NV_Ith_P(v,i) within the loop.

• N_VNewEmpty_Parallel, N_VMake_Parallel, and N_VCloneVectorArrayEmpty_Parallel set the field own_data = SUNFALSE. N_VDestroy_Parallel and N_VDestroyVectorArray_Parallel will not attempt to free the pointer data for any N_Vector with own_data set to SUNFALSE. In such a case, it is the user's responsibility to deallocate the data pointer.

• To maximize efficiency, vector operations in the NVECTOR_PARALLEL implementation that have more than one N_Vector argument do not check for consistent internal representation of these vectors. It is the user's responsibility to ensure that such routines are called with N_Vector arguments that were all created with the same internal representations.

For solvers that include a Fortran interface module, the NVECTOR_PARALLEL module also includes a Fortran-callable function FNVINITP(COMM, code, NLOCAL, NGLOBAL, IER), to initialize this NVECTOR_PARALLEL module. Here COMM is the MPI communicator, code is an input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); NLOCAL and NGLOBAL are the local and global vector sizes, respectively (declared so as to match C type long int); and IER is an error return flag equal 0 for success and -1 for failure. NOTE: If the header file sundials_config.h defines SUNDIALS_MPI_COMM_F2C to be 1 (meaning the MPI implementation used to build SUNDIALS includes the MPI_Comm_f2c function), then COMM can be any valid MPI communicator. Otherwise, MPI_COMM_WORLD will be used, so just pass an integer value as a placeholder.

6.3 The NVECTOR_OPENMP implementation

In situations where a user has a multi-core processing unit capable of running multiple parallel threads with shared memory, SUNDIALS provides an implementation of NVECTOR using OpenMP, called NVECTOR_OPENMP, and an implementation using Pthreads, called NVECTOR_PTHREADS. Testing has shown that vectors should be of length at least 100,000 before the overhead associated with creating and using the threads is made up by the parallelism in the vector calculations.

The OpenMP NVECTOR implementation provided with SUNDIALS, NVECTOR_OPENMP, defines the content field of N_Vector to be a structure containing the length of the vector, a pointer to the beginning of a contiguous data array, a boolean flag own_data which specifies the ownership of data, and the number of threads. Operations on the vector are threaded using OpenMP.

```
struct _N_VectorContent_OpenMP {
   sunindextype length;
   booleantype own_data;
   realtype *data;
   int num_threads;
};
```

The header file to include when using this module is nvector_openmp.h. The installed module library to link to is libsundials_nvecopenmp.lib where .lib is typically .so for shared libraries and .a for static libraries.

The following macros are provided to access the content of an NVECTOR_OPENMP vector. The suffix <code>LOMP</code> in the names denotes the OpenMP version.

• NV_CONTENT_OMP

This routine gives access to the contents of the OpenMP vector N_Vector.

The assignment $v_cont = NV_CONTENT_OMP(v)$ sets v_cont to be a pointer to the OpenMP N_Vector content structure.

Implementation:

```
#define NV_CONTENT_OMP(v) ( (N_VectorContent_OpenMP)(v->content) )
```

• NV_OWN_DATA_OMP, NV_DATA_OMP, NV_LENGTH_OMP, NV_NUM_THREADS_OMP

These macros give individual access to the parts of the content of a OpenMP N_Vector.

The assignment $v_{data} = NV_DATA_OMP(v)$ sets v_{data} to be a pointer to the first component of the data for the $N_vector v$. The assignment $NV_DATA_OMP(v) = v_{data}$ sets the component array of v to be v_{data} by storing the pointer v_{data} .

The assignment $v_len = NV_LENGTH_OMP(v)$ sets v_len to be the length of v. On the other hand, the call $NV_LENGTH_OMP(v) = len_v$ sets the length of v to be len_v .

The assignment $v_num_threads = NV_NUM_THREADS_OMP(v)$ sets $v_num_threads$ to be the number of threads from v. On the other hand, the call $NV_NUM_THREADS_OMP(v) = num_threads_v$ sets the number of threads for v to be $num_threads_v$.

Implementation:

```
#define NV_OWN_DATA_OMP(v) ( NV_CONTENT_OMP(v)->own_data )
#define NV_DATA_OMP(v) ( NV_CONTENT_OMP(v)->data )
#define NV_LENGTH_OMP(v) ( NV_CONTENT_OMP(v)->length )
#define NV_NUM_THREADS_OMP(v) ( NV_CONTENT_OMP(v)->num_threads )
```

• NV_Ith_OMP

This macro gives access to the individual components of the data array of an N_Vector.

The assignment $r = NV_{in}(v,i)$ sets r to be the value of the i-th component of v. The assignment $NV_{in}(v,i) = r$ sets the value of the i-th component of v to be r.

Here i ranges from 0 to n-1 for a vector of length n.

Implementation:

```
#define NV_Ith_OMP(v,i) ( NV_DATA_OMP(v)[i] )
```

The NVECTOR_OPENMP module defines OpenMP implementations of all vector operations listed in Tables 6.2, 6.3, and 6.4. Their names are obtained from those in Tables 6.2, 6.3, and 6.4 by appending the suffix _OpenMP (e.g. N_VDestroy_OpenMP). The module NVECTOR_OPENMP provides the following additional user-callable routines:

• N_VNew_OpenMP

This function creates and allocates memory for a OpenMP N_Vector. Arguments are the vector length and number of threads.

```
N_Vector N_VNew_OpenMP(sunindextype vec_length, int num_threads);
```

• N_VNewEmpty_OpenMP

This function creates a new OpenMP N_Vector with an empty (NULL) data array.

```
N_Vector N_VNewEmpty_OpenMP(sunindextype vec_length, int num_threads);
```

• N_VMake_OpenMP

This function creates and allocates memory for a OpenMP vector with user-provided data array.

(This function does *not* allocate memory for v_data itself.)

```
N_Vector N_VMake_OpenMP(sunindextype vec_length, realtype *v_data, int num_threads);
```

N_VCloneVectorArray_OpenMP

This function creates (by cloning) an array of count OpenMP vectors.

```
N_Vector *N_VCloneVectorArray_OpenMP(int count, N_Vector w);
```

• N_VCloneVectorArrayEmpty_OpenMP

This function creates (by cloning) an array of count OpenMP vectors, each with an empty (NULL) data array.

```
N_Vector *N_VCloneVectorArrayEmpty_OpenMP(int count, N_Vector w);
```

• N_VDestroyVectorArray_OpenMP

This function frees memory allocated for the array of count variables of type N_Vector created with N_VCloneVectorArray_OpenMP or with N_VCloneVectorArrayEmpty_OpenMP.

```
void N_VDestroyVectorArray_OpenMP(N_Vector *vs, int count);
```

N_VGetLength_OpenMP
This function returns number of vector elements.
sunindextype N_VGetLength_OpenMP(N_Vector v);
N_VPrint_OpenMP
This function prints the content of an OpenMP vector to stdout.
void N_VPrint_OpenMP(N_Vector v);
N_VPrintFile_OpenMP
This function prints the content of an OpenMP vector to outfile.
void N_VPrintFile_OpenMP(N_Vector v, FILE *outfile);

Notes

- When looping over the components of an N_Vector v, it is more efficient to first obtain the component array via v_data = NV_DATA_OMP(v) and then access v_data[i] within the loop than it is to use NV_Ith_OMP(v,i) within the loop.
- N_VNewEmpty_OpenMP, N_VMake_OpenMP, and N_VCloneVectorArrayEmpty_OpenMP set the field own_data = SUNFALSE. N_VDestroy_OpenMP and N_VDestroyVectorArray_OpenMP will not attempt to free the pointer data for any N_Vector with own_data set to SUNFALSE. In such a case, it is the user's responsibility to deallocate the data pointer.
- To maximize efficiency, vector operations in the NVECTOR_OPENMP implementation that have more than one N_Vector argument do not check for consistent internal representation of these vectors. It is the user's responsibility to ensure that such routines are called with N_Vector arguments that were all created with the same internal representations.

For solvers that include a Fortran interface module, the NVECTOR_OPENMP module also includes a Fortran-callable function FNVINITOMP(code, NEQ, NUMTHREADS, IER), to initialize this module. Here code is an input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); NEQ is the problem size (declared so as to match C type long int); NUMTHREADS is the number of threads; and IER is an error return flag equal 0 for success and -1 for failure.

6.4 The NVECTOR_PTHREADS implementation

In situations where a user has a multi-core processing unit capable of running multiple parallel threads with shared memory, SUNDIALS provides an implementation of NVECTOR using OpenMP, called NVECTOR_OPENMP, and an implementation using Pthreads, called NVECTOR_PTHREADS. Testing has shown that vectors should be of length at least 100,000 before the overhead associated with creating and using the threads is made up by the parallelism in the vector calculations.

The Pthreads NVECTOR implementation provided with SUNDIALS, denoted NVECTOR_PTHREADS, defines the *content* field of N_Vector to be a structure containing the length of the vector, a pointer to the beginning of a contiguous data array, a boolean flag *own_data* which specifies the ownership of *data*, and the number of threads. Operations on the vector are threaded using POSIX threads (Pthreads).

```
struct _N_VectorContent_Pthreads {
   sunindextype length;
   booleantype own_data;
   realtype *data;
   int num_threads;
};
```

The header file to include when using this module is $nvector_pthreads.h$. The installed module library to link to is $libsundials_nvecpthreads.lib$ where .lib is typically .so for shared libraries and .a for static libraries.

The following macros are provided to access the content of an NVECTOR_PTHREADS vector. The suffix _PT in the names denotes the Pthreads version.

NV_CONTENT_PT

This routine gives access to the contents of the Pthreads vector N_Vector.

The assignment $v_cont = NV_CONTENT_PT(v)$ sets v_cont to be a pointer to the Pthreads N_Vector content structure.

Implementation:

```
#define NV_CONTENT_PT(v) ( (N_VectorContent_Pthreads)(v->content) )
```

• NV_OWN_DATA_PT, NV_DATA_PT, NV_LENGTH_PT, NV_NUM_THREADS_PT

These macros give individual access to the parts of the content of a Pthreads N_Vector.

The assignment $v_{data} = NV_DATA_PT(v)$ sets v_{data} to be a pointer to the first component of the data for the $N_Vector v$. The assignment $NV_DATA_PT(v) = v_{data}$ sets the component array of v to be v_{data} by storing the pointer v_{data} .

The assignment $v_len = NV_LENGTH_PT(v)$ sets v_len to be the length of v. On the other hand, the call $NV_LENGTH_PT(v) = len_v$ sets the length of v to be len_v .

The assignment v_num_threads = NV_NUM_THREADS_PT(v) sets v_num_threads to be the number of threads from v. On the other hand, the call NV_NUM_THREADS_PT(v) = num_threads_v sets the number of threads for v to be num_threads_v.

Implementation:

```
#define NV_OWN_DATA_PT(v) ( NV_CONTENT_PT(v)->own_data )
#define NV_DATA_PT(v) ( NV_CONTENT_PT(v)->data )
#define NV_LENGTH_PT(v) ( NV_CONTENT_PT(v)->length )
#define NV_NUM_THREADS_PT(v) ( NV_CONTENT_PT(v)->num_threads )
```

• NV_Ith_PT

This macro gives access to the individual components of the data array of an N_Vector.

The assignment $r = NV_{int}PT(v,i)$ sets r to be the value of the i-th component of v. The assignment $NV_{int}PT(v,i) = r$ sets the value of the i-th component of v to be r.

Here i ranges from 0 to n-1 for a vector of length n.

Implementation:

```
#define NV_Ith_PT(v,i) ( NV_DATA_PT(v)[i] )
```

The NVECTOR_PTHREADS module defines Pthreads implementations of all vector operations listed in Tables 6.2, 6.3, and 6.4. Their names are obtained from those in Tables 6.2, 6.3, and 6.4 by appending the suffix _Pthreads (e.g. N_VDestroy_Pthreads). The module NVECTOR_PTHREADS provides the following additional user-callable routines:

• N_VNew_Pthreads

This function creates and allocates memory for a Pthreads N_Vector. Arguments are the vector length and number of threads.

N_Vector N_VNew_Pthreads(sunindextype vec_length, int num_threads);

• N_VNewEmpty_Pthreads

This function creates a new Pthreads N_Vector with an empty (NULL) data array.

```
N_Vector N_VNewEmpty_Pthreads(sunindextype vec_length, int num_threads);
```

• N_VMake_Pthreads

This function creates and allocates memory for a Pthreads vector with user-provided data array.

(This function does *not* allocate memory for v_data itself.)

N_Vector N_VMake_Pthreads(sunindextype vec_length, realtype *v_data, int num_threads);

• N_VCloneVectorArray_Pthreads

This function creates (by cloning) an array of count Pthreads vectors.

N_Vector *N_VCloneVectorArray_Pthreads(int count, N_Vector w);

• N_VCloneVectorArrayEmpty_Pthreads

This function creates (by cloning) an array of count Pthreads vectors, each with an empty (NULL) data array.

N_Vector *N_VCloneVectorArrayEmpty_Pthreads(int count, N_Vector w);

• N_VDestroyVectorArray_Pthreads

This function frees memory allocated for the array of count variables of type N_Vector created with N_VCloneVectorArray_Pthreads or with N_VCloneVectorArrayEmpty_Pthreads.

void N_VDestroyVectorArray_Pthreads(N_Vector *vs, int count);

• N_VGetLength_Pthreads

This function returns the number of vector elements.

sunindextype N_VGetLength_Pthreads(N_Vector v);

• N_VPrint_Pthreads

This function prints the content of a Pthreads vector to stdout.

```
void N_VPrint_Pthreads(N_Vector v);
```

• N_VPrintFile_Pthreads

This function prints the content of a Pthreads vector to outfile.

```
void N_VPrintFile_Pthreads(N_Vector v, FILE *outfile);
```

Notes

- When looping over the components of an N_Vector v, it is more efficient to first obtain the component array via v_data = NV_DATA_PT(v) and then access v_data[i] within the loop than it is to use NV_Ith_PT(v,i) within the loop.
- N_VNewEmpty_Pthreads, N_VMake_Pthreads, and N_VCloneVectorArrayEmpty_Pthreads set the field own_data = SUNFALSE. N_VDestroy_Pthreads and N_VDestroyVectorArray_Pthreads will not attempt to free the pointer data for any N_Vector with own_data set to SUNFALSE. In such a case, it is the user's responsibility to deallocate the data pointer.
- To maximize efficiency, vector operations in the NVECTOR_PTHREADS implementation that have more than one N_Vector argument do not check for consistent internal representation of these vectors. It is the user's responsibility to ensure that such routines are called with N_Vector arguments that were all created with the same internal representations.

For solvers that include a Fortran interface module, the NVECTOR_PTHREADS module also includes a Fortran-callable function FNVINITPTS(code, NEQ, NUMTHREADS, IER), to initialize this module. Here code is an input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); NEQ is the problem size (declared so as to match C type long int); NUMTHREADS is the number of threads; and IER is an error return flag equal 0 for success and -1 for failure.

6.5 The NVECTOR_PARHYP implementation

The NVECTOR_PARHYP implementation of the NVECTOR module provided with SUNDIALS is a wrapper around *hypre*'s ParVector class. Most of the vector kernels simply call *hypre* vector operations. The implementation defines the *content* field of N_Vector to be a structure containing the global and local lengths of the vector, a pointer to an object of type hypre_ParVector, an MPI communicator, and a boolean flag *own_parvector* indicating ownership of the *hypre* parallel vector object *x*.

```
struct _N_VectorContent_ParHyp {
   sunindextype local_length;
   sunindextype global_length;
   booleantype own_parvector;
   MPI_Comm comm;
   hypre_ParVector *x;
};
```

The header file to include when using this module is nvector_parhyp.h. The installed module library to link to is libsundials_nvecparhyp.lib where .lib is typically .so for shared libraries and .a for static libraries.

Unlike native SUNDIALS vector types, NVECTOR_PARHYP does not provide macros to access its member variables. Note that NVECTOR_PARHYP requires SUNDIALS to be built with MPI support.

The NVECTOR_PARHYP module defines implementations of all vector operations listed in Tables 6.2, 6.3, and 6.4, except for N_VSetArrayPointer and N_VGetArrayPointer, because accessing raw vector data is handled by low-level *hypre* functions. As such, this vector is not available for use with SUNDIALS Fortran interfaces. When access to raw vector data is needed, one should extract the *hypre* vector first, and then use *hypre* methods to access the data. Usage examples of NVECTOR_PARHYP are provided in the cvAdvDiff_non_ph.c example program for CVODE [27] and the ark_diurnal_kry_ph.c example program for ARKODE [34].

The names of parhyp methods are obtained from those in Tables 6.2, 6.3, and 6.4 by appending the suffix Parhyp (e.g. N_VDestroy_Parhyp). The module NVECTOR_PARHYP provides the following additional user-callable routines:

• N_VNewEmpty_ParHyp

This function creates a new parhyp N_Vector with the pointer to the hypre vector set to NULL.

N_VMake_ParHyp

This function creates an N_Vector wrapper around an existing hypre parallel vector. It does not allocate memory for x itself.

```
N_Vector N_VMake_ParHyp(hypre_ParVector *x);
```

• N_VGetVector_ParHyp

This function returns a pointer to the underlying *hypre* vector. hypre_ParVector *N_VGetVector_ParHyp(N_Vector v);

• N_VCloneVectorArray_ParHyp

This function creates (by cloning) an array of count parallel vectors.

```
N_Vector *N_VCloneVectorArray_ParHyp(int count, N_Vector w);
```

• N_VCloneVectorArrayEmpty_ParHyp

This function creates (by cloning) an array of count parallel vectors, each with an empty (NULL) data array.

```
N_Vector *N_VCloneVectorArrayEmpty_ParHyp(int count, N_Vector w);
```

• N_VDestroyVectorArray_ParHyp

This function frees memory allocated for the array of count variables of type N_Vector created with N_VCloneVectorArray_ParHyp or with N_VCloneVectorArrayEmpty_ParHyp.

```
void N_VDestroyVectorArray_ParHyp(N_Vector *vs, int count);
```

N_VPrint_ParHyp

This function prints the local content of a parhyp vector to stdout.

```
void N_VPrint_ParHyp(N_Vector v);
```

• N_VPrintFile_ParHyp

This function prints the local content of a parhyp vector to outfile.

```
void N_VPrintFile_ParHyp(N_Vector v, FILE *outfile);
```

Notes

- When there is a need to access components of an N_Vector_ParHyp, v, it is recommended to extract the hypre vector via x_vec = N_VGetVector_ParHyp(v) and then access components using appropriate hypre functions.
- N_VNewEmpty_ParHyp, N_VMake_ParHyp, and N_VCloneVectorArrayEmpty_ParHyp set the field own_parvector to SUNFALSE. N_VDestroy_ParHyp and N_VDestroyVectorArray_ParHyp will not attempt to delete an underlying hypre vector for any N_Vector with own_parvector set to SUNFALSE. In such a case, it is the user's responsibility to delete the underlying vector.
- To maximize efficiency, vector operations in the NVECTOR_PARHYP implementation that have more than one N_Vector argument do not check for consistent internal representations of these vectors. It is the user's responsibility to ensure that such routines are called with N_Vector arguments that were all created with the same internal representations.

6.6 The NVECTOR_PETSC implementation

The NVECTOR_PETSC module is an NVECTOR wrapper around the PETSc vector. It defines the *content* field of a N_Vector to be a structure containing the global and local lengths of the vector, a pointer to the PETSc vector, an MPI communicator, and a boolean flag own_data indicating ownership of the wrapped PETSc vector.

```
struct _N_VectorContent_Petsc {
   sunindextype local_length;
   sunindextype global_length;
   booleantype own_data;
   Vec *pvec;
   MPI_Comm comm;
};
```

The header file to include when using this module is nvector_petsc.h. The installed module library to link to is libsundials_nvecpetsc.lib where .lib is typically .so for shared libraries and .a for static libraries.

Unlike native SUNDIALS vector types, NVECTOR_PETSC does not provide macros to access its member variables. Note that NVECTOR_PETSC requires SUNDIALS to be built with MPI support.

The NVECTOR_PETSC module defines implementations of all vector operations listed in Tables 6.2, 6.3, and 6.4, except for N_VGetArrayPointer and N_VSetArrayPointer. As such, this vector cannot be used with SUNDIALS Fortran interfaces. When access to raw vector data is needed, it is recommended to extract the PETSc vector first, and then use PETSc methods to access the data. Usage examples of NVECTOR_PETSC are provided in example programs for IDA [26].

The names of vector operations are obtained from those in Tables 6.2, 6.3, and 6.4 by appending the suffix _Petsc (e.g. N_VDestroy_Petsc). The module NVECTOR_PETSC provides the following additional user-callable routines:

• N_VNewEmpty_Petsc

This function creates a new NVECTOR wrapper with the pointer to the wrapped PETSc vector set to (NULL). It is used by the N_VMake_Petsc and N_VClone_Petsc implementations.

• N_VMake_Petsc

This function creates and allocates memory for an NVECTOR_PETSC wrapper around a user-provided PETSc vector. It does *not* allocate memory for the vector pvec itself.

```
N_Vector N_VMake_Petsc(Vec *pvec);
```

• N_VGetVector_Petsc

This function returns a pointer to the underlying PETSc vector.

```
Vec *N_VGetVector_Petsc(N_Vector v);
```

• N_VCloneVectorArray_Petsc

This function creates (by cloning) an array of count NVECTOR_PETSC vectors.

```
N_Vector *N_VCloneVectorArray_Petsc(int count, N_Vector w);
```

• N_VCloneVectorArrayEmpty_Petsc

This function creates (by cloning) an array of count NVECTOR_PETSC vectors, each with pointers to PETSC vectors set to (NULL).

```
N_Vector *N_VCloneVectorArrayEmpty_Petsc(int count, N_Vector w);
```

• N_VDestroyVectorArray_Petsc

This function frees memory allocated for the array of count variables of type N_Vector created with N_VCloneVectorArray_Petsc or with N_VCloneVectorArray_Empty_Petsc.

```
void N_VDestroyVectorArray_Petsc(N_Vector *vs, int count);
```

• N_VPrint_Petsc

This function prints the global content of a wrapped PETSc vector to stdout. void N_VPrint_Petsc(N_Vector v);

• N_VPrintFile_Petsc

This function prints the global content of a wrapped PETSc vector to fname.

```
void N_VPrintFile_Petsc(N_Vector v, const char fname[]);
```

Notes

- When there is a need to access components of an N_Vector_Petsc, v, it is recommeded to extract the PETSc vector via x_vec = N_VGetVector_Petsc(v) and then access components using appropriate PETSc functions.
- The functions N_VNewEmpty_Petsc, N_VMake_Petsc, and N_VCloneVectorArrayEmpty_Petsc set the field own_data to SUNFALSE. N_VDestroy_Petsc and N_VDestroyVectorArray_Petsc will not attempt to free the pointer pvec for any N_Vector with own_data set to SUNFALSE. In such a case, it is the user's responsibility to deallocate the pvec pointer.
- To maximize efficiency, vector operations in the NVECTOR_PETSC implementation that have more than one N_Vector argument do not check for consistent internal representations of these vectors. It is the user's responsibility to ensure that such routines are called with N_Vector arguments that were all created with the same internal representations.

6.7 The NVECTOR_CUDA implementation

The NVECTOR_CUDA module is an experimental NVECTOR implementation in the CUDA language. The module allows for SUNDIALS vector kernels to run on GPU devices. It is intended for users who are already familiar with CUDA and GPU programming. Building this vector module requires a CUDA compiler and, by extension, a C++ compiler. The class Vector in namespace suncudavec manages vector data layout:

```
template <class T, class I>
class Vector {
    I size_;
    I mem_size_;
    T* h_vec_;
    T* d_vec_;
    StreamPartitioning<T, I>* partStream_;
    ReducePartitioning<T, I>* partReduce_;
    bool ownPartitioning_;
    ...
};
```

The class members are vector size (length), size of the vector data memory block, pointers to vector data on the host and the device, pointers to classes StreamPartitioning and ReducePartitioning, which handle thread partitioning for streaming and reduction vector kernels, respectively, and a boolean flag that signals if the vector owns the thread partitioning. The class Vector inherits from the empty structure

```
struct _N_VectorContent_Cuda {
};
```

to interface the C++ class with the NVECTOR C code. When instantiated, the class Vector will allocate memory on both the host and the device. Due to the rapid progress of CUDA development, we expect that the suncudavec::Vector class will change frequently in future SUNDIALS releases. The code is structured so that it can tolerate significant changes in the suncudavec::Vector class without requiring changes to the user API.

The header file to include when using this module is nvector_cuda.h. The installed module library to link to is libsundials_nveccuda.lib where .lib is typically .so for shared libraries and .a for static libraries.

Unlike other native SUNDIALS vector types, NVECTOR_CUDA does not provide macros to access its member variables.

The NVECTOR_CUDA module defines implementations of all vector operations listed in Tables 6.2, 6.3, and 6.4, except for N_VGetArrayPointer and N_VSetArrayPointer. As such, this vector cannot be used with SUNDIALS Fortran interfaces, nor with SUNDIALS direct solvers and preconditioners. This support will be added in subsequent SUNDIALS releases. The NVECTOR_CUDA module provides separate functions to access data on the host and on the device. It also provides methods for copying from the host to the device and vice versa. Usage examples of NVECTOR_CUDA are provided in some example programs for CVODE [27].

The names of vector operations are obtained from those in Tables 6.2, 6.3, and 6.4 by appending the suffix _Cuda (e.g. N_VDestroy_Cuda). The module NVECTOR_CUDA provides the following additional user-callable routines:

• N_VNew_Cuda

This function creates and allocates memory for a CUDA N_Vector. The memory is allocated on both host and device. Its only argument is the vector length.

N_Vector N_VNew_Cuda(sunindextype vec_length);

• N_VNewEmpty_Cuda

This function creates a new NVECTOR wrapper with the pointer to the wrapped CUDA vector set to (NULL). It is used by the N_VNew_Cuda, N_VMake_Cuda, and N_VClone_Cuda implementations.

N_Vector N_VNewEmpty_Cuda(sunindextype vec_length);

• N_VMake_Cuda

This function creates and allocates memory for an NVECTOR_CUDA wrapper around a user-provided suncudavec::Vector class. Its only argument is of type N_VectorContent_Cuda, which is the pointer to the class.

N_Vector N_VMake_Cuda(N_VectorContent_Cuda c);

• N_VCloneVectorArray_Cuda

This function creates (by cloning) an array of count NVECTOR_CUDA vectors.

N_Vector *N_VCloneVectorArray_Cuda(int count, N_Vector w);

• N_VCloneVectorArrayEmpty_Cuda

This function creates (by cloning) an array of count NVECTOR_CUDA vectors, each with pointers to CUDA vectors set to (NULL).

N_Vector *N_VCloneVectorArrayEmpty_Cuda(int count, N_Vector w);

• N_VDestroyVectorArray_Cuda

This function frees memory allocated for the array of count variables of type N_Vector created with N_VCloneVectorArray_Cuda or with N_VCloneVectorArrayEmpty_Cuda.

void N_VDestroyVectorArray_Cuda(N_Vector *vs, int count);

• N_VGetLength_Cuda

This function returns the length of the vector.

sunindextype N_VGetLength_Cuda(N_Vector v);

• N_VGetHostArrayPointer_Cuda

```
This function returns a pointer to the vector data on the host. realtype *N_VGetHostArrayPointer_Cuda(N_Vector v);
```

• N_VGetDeviceArrayPointer_Cuda

```
This function returns a pointer to the vector data on the device.
realtype *N_VGetDeviceArrayPointer_Cuda(N_Vector v);
```

• N_VCopyToDevice_Cuda

```
This function copies host vector data to the device. realtype *N_VCopyToDevice_Cuda(N_Vector v);
```

• N_VCopyFromDevice_Cuda

```
This function copies vector data from the device to the host.

realtype *N_VCopyFromDevice_Cuda(N_Vector v);
```

• N_VPrint_Cuda

```
This function prints the content of a CUDA vector to stdout. void N_VPrint_Cuda(N_Vector v);
```

• N_VPrintFile_Cuda

```
This function prints the content of a CUDA vector to outfile. void N_VPrintFile_Cuda(N_Vector v, FILE *outfile);
```

Notes

- When there is a need to access components of an N_Vector_Cuda, v, it is recommeded to use functions N_VGetDeviceArrayPointer_Cuda or N_VGetHostArrayPointer_Cuda.
- To maximize efficiency, vector operations in the NVECTOR_CUDA implementation that have more than one N_Vector argument do not check for consistent internal representations of these vectors. It is the user's responsibility to ensure that such routines are called with N_Vector arguments that were all created with the same internal representations.

6.8 The NVECTOR_RAJA implementation

The NVECTOR_RAJA module is an experimental NVECTOR implementation using the RAJA hardware abstraction layer, https://software.llnl.gov/RAJA/. In this implementation, RAJA allows for SUNDIALS vector kernels to run on GPU devices. The module is intended for users who are already familiar with RAJA and GPU programming. Building this vector module requires a C++11 compliant compiler and a CUDA software development toolkit. Besides the CUDA backend, RAJA has other backends such as serial, OpenMP, and OpenAC. These backends are not used in this SUNDIALS release. Class Vector in namespace sunrajavec manages the vector data layout:

```
template <class T, class I>
class Vector {
    I size_;
    I mem_size_;
    T* h_vec_;
    T* d_vec_;
    ...
};
```

The class members are: vector size (length), size of the vector data memory block, and pointers to vector data on the host and on the device. The class Vector inherits from an empty structure

```
struct _N_VectorContent_Raja {
};
```

to interface the C++ class with the NVECTOR C code. When instantiated, the class Vector will allocate memory on both the host and the device. Due to the rapid progress of RAJA development, we expect that the sunrajavec::Vector class will change frequently in future SUNDIALS releases. The code is structured so that it can tolerate significant changes in the sunrajavec::Vector class without requiring changes to the user API.

The header file to include when using this module is nvector_raja.h. The installed module library to link to is libsundials_nvecraja.lib where .lib is typically .so for shared libraries and .a for static libraries.

Unlike other native SUNDIALS vector types, NVECTOR_RAJA does not provide macros to access its member variables.

The NVECTOR_RAJA module defines the implementations of all vector operations listed in Tables 6.2, 6.3, and 6.4, except for N_VDotProdMulti, N_VWrmsNormVectorArray, and N_VWrmsNormMaskVectorArray as support for arrays of reduction vectors is not yet supported in RAJA. These function will be added to the NVECTOR_RAJA implementation in the futrue. Additionally vector N_VGetArrayPointer and N_VSetArrayPointer are not implemented by the RAJA vector. As such, this vector cannot be used with SUNDIALS Fortran interfaces, nor with SUNDIALS direct solvers and preconditioners. The NVECTOR_RAJA module provides separate functions to access data on the host and on the device. It also provides methods for copying data from the host to the device and vice versa. Usage examples of NVECTOR_RAJA are provided in some example programs for CVODE [27].

The names of vector operations are obtained from those in Tables 6.2, 6.3, and 6.4, by appending the suffix Raja (e.g. N_VDestroy_Raja). The module NVECTOR_RAJA provides the following additional user-callable routines:

• N_VNew_Raja

This function creates and allocates memory for a RAJA N_Vector. The memory is allocated on both the host and the device. Its only argument is the vector length.

```
N_Vector N_VNew_Raja(sunindextype vec_length);
```

• N_VNewEmpty_Raja

This function creates a new NVECTOR wrapper with the pointer to the wrapped RAJA vector set to (NULL). It is used by the N_VNew_Raja, N_VMake_Raja, and N_VClone_Raja implementations.

```
N_Vector N_VNewEmpty_Raja(sunindextype vec_length);
```

• N_VMake_Raja

This function creates and allocates memory for an NVECTOR_RAJA wrapper around a user-provided sunrajavec::Vector class. Its only argument is of type N_VectorContent_Raja, which is the pointer to the class.

```
N_Vector N_VMake_Raja(N_VectorContent_Raja c);
```

• N_VCloneVectorArray_Raja

This function creates (by cloning) an array of count NVECTOR_RAJA vectors.

```
N_Vector *N_VCloneVectorArray_Raja(int count, N_Vector w);
```

• N_VCloneVectorArrayEmpty_Raja

This function creates (by cloning) an array of count NVECTOR_RAJA vectors, each with pointers to RAJA vectors set to (NULL).

```
N_Vector *N_VCloneVectorArrayEmpty_Raja(int count, N_Vector w);
```

• N_VDestroyVectorArray_Raja

This function frees memory allocated for the array of count variables of type N_Vector created with N_VCloneVectorArray_Raja or with N_VCloneVectorArrayEmpty_Raja.

```
void N_VDestroyVectorArray_Raja(N_Vector *vs, int count);
```

• N_VGetLength_Raja

This function returns the length of the vector.

```
sunindextype N_VGetLength_Raja(N_Vector v);
```

• N_VGetHostArrayPointer_Raja

This function returns a pointer to the vector data on the host.

```
realtype *N_VGetHostArrayPointer_Raja(N_Vector v);
```

• N_VGetDeviceArrayPointer_Raja

This function returns a pointer to the vector data on the device.

```
realtype *N_VGetDeviceArrayPointer_Raja(N_Vector v);
```

• N_VCopyToDevice_Raja

This function copies host vector data to the device.

```
realtype *N_VCopyToDevice_Raja(N_Vector v);
```

• N_VCopyFromDevice_Raja

This function copies vector data from the device to the host.

```
realtype *N_VCopyFromDevice_Raja(N_Vector v);
```

• N_VPrint_Raja

This function prints the content of a RAJA vector to stdout.

```
void N_VPrint_Raja(N_Vector v);
```

• N_VPrintFile_Raja

This function prints the content of a RAJA vector to outfile.

```
void N_VPrintFile_Raja(N_Vector v, FILE *outfile);
```

Notes

- When there is a need to access components of an N_Vector_Raja, v, it is recommeded to use functions N_VGetDeviceArrayPointer_Raja or N_VGetHostArrayPointer_Raja.
- To maximize efficiency, vector operations in the NVECTOR_RAJA implementation that have more than one N_Vector argument do not check for consistent internal representations of these vectors. It is the user's responsibility to ensure that such routines are called with N_Vector arguments that were all created with the same internal representations.

6.9 NVECTOR Examples

There are NVector examples that may be installed for the implementations provided with SUNDIALS. Each implementation makes use of the functions in test_nvector.c. These example functions show simple usage of the NVector family of functions. The input to the examples are the vector length, number of threads (if threaded implementation), and a print timing flag.

The following is a list of the example functions in test_nvector.c:

- Test_N_VClone: Creates clone of vector and checks validity of clone.
- Test_N_VCloneEmpty: Creates clone of empty vector and checks validity of clone.
- Test_N_VCloneVectorArray: Creates clone of vector array and checks validity of cloned array.
- Test_N_VCloneVectorArray: Creates clone of empty vector array and checks validity of cloned array.
- Test_N_VGetArrayPointer: Get array pointer.
- Test_N_VSetArrayPointer: Allocate new vector, set pointer to new vector array, and check values.
- Test_N_VLinearSum Case 1a: Test y = x + y
- Test_N_VLinearSum Case 1b: Test y = -x + y
- Test_N_VLinearSum Case 1c: Test y = ax + y
- Test_N_VLinearSum Case 2a: Test x = x + y
- Test_N_VLinearSum Case 2b: Test x = x y
- Test_N_VLinearSum Case 2c: Test x = x + by
- Test_N_VLinearSum Case 3: Test z = x + y
- Test_N_VLinearSum Case 4a: Test z = x y
- Test_N_VLinearSum Case 4b: Test z = -x + y
- Test_N_VLinearSum Case 5b: Test z = ax + y
- Test_N_VLinearSum Case 6a: Test z = -x + by
- Test_N_VLinearSum Case 6b: Test z = ax y
- Test_N_VLinearSum Case 7: Test z = a(x + y)
- Test_N_VLinearSum Case 8: Test z = a(x y)
- Test_N_VLinearSum Case 9: Test z = ax + by
- Test_N_VConst: Fill vector with constant and check result.
- Test_N_VProd: Test vector multiply: z = x * y
- Test_N_VDiv: Test vector division: z = x / y
- Test_N_VScale: Case 1: scale: x = cx
- Test_N_VScale: Case 2: copy: z = x

- Test_N_VScale: Case 3: negate: z = -x
- Test_N_VScale: Case 4: combination: z = cx
- Test_N_VAbs: Create absolute value of vector.
- Test_N_VAddConst: add constant vector: z = c + x
- Test_N_VDotProd: Calculate dot product of two vectors.
- Test_N_VMaxNorm: Create vector with known values, find and validate the max norm.
- Test_N_VWrmsNorm: Create vector of known values, find and validate the weighted root mean square.
- Test_N_VWrmsNormMask: Create vector of known values, find and validate the weighted root mean square using all elements except one.
- Test_N_VMin: Create vector, find and validate the min.
- Test_N_VWL2Norm: Create vector, find and validate the weighted Euclidean L2 norm.
- Test_N_VL1Norm: Create vector, find and validate the L1 norm.
- Test_N_VCompare: Compare vector with constant returning and validating comparison vector.
- Test_N_VInvTest: Test z[i] = 1 / x[i]
- Test_N_VConstrMask: Test mask of vector x with vector c.
- Test_N_VMinQuotient: Fill two vectors with known values. Calculate and validate minimum quotient.
- Test_N_VLinearCombination Case 1a: Test x = a x
- Test_N_VLinearCombination Case 1b: Test z = a x
- Test_N_VLinearCombination Case 2a: Test x = a x + b y
- Test_N_VLinearCombination Case 2b: Test z = a x + b y
- Test_N_VLinearCombination Case 3a: Test x = x + a y + b z
- Test_N_VLinearCombination Case 3c: Test w = a x + b y + c z
- Test_N_VScaleAddMulti Case 1a: y = a x + y
- Test_N_VScaleAddMulti Case 1b: z = a x + y
- Test_N_VScaleAddMulti Case 2a: Y[i] = c[i] x + Y[i], i = 1,2,3
- Test_N_VScaleAddMulti Case 2b: $Z[i] = c[i] \times Y[i]$, i = 1,2,3
- Test_N_VDotProdMulti Case 1: Calculate the dot product of two vectors
- Test_N_VDotProdMulti Case 2: Calculate the dot product of one vector with three other vectors in a vector array.
- Test_N_VLinearSumVectorArray Case 1: z = a x + b y
- Test_N_VLinearSumVectorArray Case 2a: Z[i] = a X[i] + b Y[i]

- Test_N_VLinearSumVectorArray Case 2c: Y[i] = a X[i] + b Y[i]
- Test_N_VScaleVectorArray Case 1a: y = c y
- Test_N_VScaleVectorArray Case 1b: z = c y
- Test_N_VScaleVectorArray Case 2a: Y[i] = c[i] Y[i]
- ullet Test_N_VScaleVectorArray Case 1a: z=c
- Test_N_VScaleVectorArray Case 1b: Z[i] = c
- Test_N_VWrmsNormVectorArray Case 1a: Create a vector of know values, find and validate the weighted root mean square norm.
- Test_N_VWrmsNormVectorArray Case 1b: Create a vector array of three vectors of know values, find and validate the weighted root mean square norm of each.
- Test_N_VWrmsNormMaskVectorArray Case 1a: Create a vector of know values, find and validate the weighted root mean square norm using all elements except one.
- Test_N_VWrmsNormMaskVectorArray Case 1b: Create a vector array of three vectors of know values, find and validate the weighted root mean square norm of each using all elements except one.
- Test_N_VScaleAddMultiVectorArray Case 1a: y = a x + y
- Test_N_VScaleAddMultiVectorArray Case 1b: z = a x + y
- Test_N_VScaleAddMultiVectorArray Case 2a: Y[j][0] = a[j] X[0] + Y[j][0]
- Test_N_VScaleAddMultiVectorArray Case 3a: Y[0][i] = a[0] X[i] + Y[0][i]
- Test_N_VScaleAddMultiVectorArray Case 3b: Z[0][i] = a[0] X[i] + Y[0][i]
- Test_N_VScaleAddMultiVectorArray Case 4a: Y[j][i] = a[j] X[i] + Y[j][i]
- Test_N_VScaleAddMultiVectorArray Case 4b: Z[i][i] = a[j] X[i] + Y[j][i]

- Test_N_VLinearCombinationVectorArray Case 2a: x = a x + b y
- Test_N_VLinearCombinationVectorArray Case 2b: z = a x + b y
- Test_N_VLinearCombinationVectorArray Case 3a: x = a x + b y + c z
- Test_N_VLinearCombinationVectorArray Case 3b: w = a x + b y + c z
- Test_N_VLinearCombinationVectorArray Case 4a: X[0][i] = c[0] X[0][i]
- Test_N_VLinearCombinationVectorArray Case 5a: X[0][i] = c[0] X[0][i] + c[1] X[1][i]
- Test_N_VLinearCombinationVectorArray Case 5b: Z[i] = c[0] X[0][i] + c[1] X[1][i]
- $\bullet \ \, \mathsf{Test_N_VLinearCombinationVectorArray} \ \, \mathsf{Case} \ \, 6a: \ \, \mathsf{X}[0][i] = \mathsf{X}[0][i] + \mathsf{c}[1] \ \, \mathsf{X}[1][i] + \mathsf{c}[2] \ \, \mathsf{X}[2][i]$
- Test_N_VLinearCombinationVectorArray Case 6b: $X[0][i] = c[0] \ X[0][i] + c[1] \ X[1][i] + c[2] \ X[2][i]$
- Test_N_VLinearCombinationVectorArray Case 6c: Z[i] = c[0] X[0][i] + c[1] X[1][i] + c[2] X[2][i]

6.10 NVECTOR functions used by CVODE

In Table 6.5 below, we list the vector functions in the NVECTOR module used within the CVODE package. The table also shows, for each function, which of the code modules uses the function. The CVODE column shows function usage within the main integrator module, while the remaining columns show function usage within each of the CVODE linear solver interfaces, the CVBANDPRE and CVBBDPRE preconditioner modules, and the FCVODE module. Here CVDLS stands for the direct linear solver interface in CVODE; CVSPILS stands for the scaled, preconditioned, iterative linear solver interface in CVODE.

At this point, we should emphasize that the CVODE user does not need to know anything about the usage of vector functions by the CVODE code modules in order to use CVODE. The information is presented as an implementation detail for the interested reader.

	CVODE	CVDLS	CVDIAG	CVSPILS	CVBANDPRE	CVBBDPRE	FCVODE
N_VGetVectorID							
$N_{-}VClone$	√		√	√			
$N_{VCloneEmpty}$							\checkmark
N_VDestroy	√		√	√			
N_VSpace	√						
$N_{-}VGetArrayPointer$		√			√	✓	\checkmark
$N_{-}VSetArrayPointer$		√					\checkmark
$N_{-}VLinearSum$	√	√	✓	√

N_VScaleVectorArray	√						

Table 6.5: List of vector functions usage by CVODE code modules

The vector functions listed in Table 6.2 that are *not* used by CVODE are: N_VWL2Norm, N_VL1Norm, N_VWrmsNormMask, N_VConstrMask, and N_VMinQuotient. Therefore, a user-supplied NVECTOR module for CVODE could omit these functions.

The optional function N_VDotProdMulti is only used when Classical Gram-Schmidt is enabled with SPGMR or SPFGMR. The remaining operations from Tables 6.3 and 6.4 not listed above are unused and a user-supplied NVECTOR module for CVODE could omit these operations.

Chapter 7

Description of the SUNMatrix module

For problems that involve direct methods for solving linear systems, the SUNDIALS solvers not only operate on generic vectors, but also on generic matrices (of type SUNMatrix), through a set of operations defined by the particular SUNMATRIX implementation. Users can provide their own specific implementation of the SUNMATRIX module, particularly in cases where they provide their own NVECTOR and/or linear solver modules, and require matrices that are compatible with those implementations. Alternately, we provide three SUNMATRIX implementations: dense, banded, and sparse. The generic operations are described below, and descriptions of the implementations provided with SUNDIALS follow.

The generic SUNMatrix type has been modeled after the object-oriented style of the generic N_Vector type. Specifically, a generic SUNMatrix is a pointer to a structure that has an implementation-dependent *content* field containing the description and actual data of the matrix, and an *ops* field pointing to a structure with generic matrix operations. The type SUNMatrix is defined as

```
typedef struct _generic_SUNMatrix *SUNMatrix;
struct _generic_SUNMatrix {
    void *content;
    struct _generic_SUNMatrix_Ops *ops;
};
```

The _generic_SUNMatrix_Ops structure is essentially a list of pointers to the various actual matrix operations, and is defined as

```
struct _generic_SUNMatrix_Ops {
  SUNMatrix_ID (*getid)(SUNMatrix);
  SUNMatrix
               (*clone)(SUNMatrix);
  void
               (*destroy)(SUNMatrix);
  int
               (*zero)(SUNMatrix);
  int
               (*copy)(SUNMatrix, SUNMatrix);
               (*scaleadd)(realtype, SUNMatrix, SUNMatrix);
  int
  int
               (*scaleaddi)(realtype, SUNMatrix);
  int
               (*matvec)(SUNMatrix, N_Vector, N_Vector);
  int
               (*space)(SUNMatrix, long int*, long int*);
};
```

The generic SUNMATRIX module defines and implements the matrix operations acting on SUNMatrix objects. These routines are nothing but wrappers for the matrix operations defined by a particular SUNMATRIX implementation, which are accessed through the *ops* field of the SUNMatrix structure. To

Matrix ID	Matrix type	ID Value
SUNMATRIX_DENSE	Dense $M \times N$ matrix	0
SUNMATRIX_BAND	Band $M \times M$ matrix	1
SUNMATRIX_SPARSE	Sparse (CSR or CSC) $M \times N$ matrix	2
SUNMATRIX_CUSTOM	User-provided custom matrix	3

Table 7.1: Identifiers associated with matrix kernels supplied with SUNDIALS.

illustrate this point we show below the implementation of a typical matrix operation from the generic SUNMATRIX module, namely SUNMatZero, which sets all values of a matrix A to zero, returning a flag denoting a successful/failed operation:

```
int SUNMatZero(SUNMatrix A)
{
  return((int) A->ops->zero(A));
}
```

Table 7.2 contains a complete list of all matrix operations defined by the generic SUNMATRIX module. A particular implementation of the SUNMATRIX module must:

- Specify the *content* field of the SUNMatrix object.
- Define and implement a minimal subset of the matrix operations. See the documentation for each SUNDIALS solver to determine which SUNMATRIX operations they require.
 - Note that the names of these routines should be unique to that implementation in order to permit using more than one SUNMATRIX module (each with different SUNMatrix internal data representations) in the same code.
- Define and implement user-callable constructor and destructor routines to create and free a SUNMatrix with the new *content* field and with *ops* pointing to the new matrix operations.
- Optionally, define and implement additional user-callable routines acting on the newly defined SUNMatrix (e.g., a routine to print the content for debugging purposes).
- Optionally, provide accessor macros or functions as needed for that particular implementation to access different parts of the *content* field of the newly defined SUNMatrix.

Each SUNMATRIX implementation included in SUNDIALS has a unique identifier specified in enumeration and shown in Table 7.1. It is recommended that a user-supplied SUNMATRIX implementation use the SUNMATRIX_CUSTOM identifier.

Name	Usage and Description
SUNMatGetID	id = SUNMatGetID(A); Returns the type identifier for the matrix A. It is used to determine the matrix implementation type (e.g. dense, banded, sparse,) from the abstract SUNMatrix interface. This is used to assess compatibility with SUNDIALS-provided linear solver implementations. Returned values are given in the Table 7.1.
	continued on next page

Table 7.2: Description of the SUNMatrix operations

Name	Usage and Description
SUNMatClone	B = SUNMatClone(A); Creates a new SUNMatrix of the same type as an existing matrix A and sets the <i>ops</i> field. It does not copy the matrix, but rather allocates storage for the new matrix.
SUNMatDestroy	SUNMatDestroy(A); Destroys the SUNMatrix A and frees memory allocated for its internal data.
SUNMatSpace	ier = SUNMatSpace(A, &lrw, &liw); Returns the storage requirements for the matrix A. lrw is a long int containing the number of realtype words and liw is a long int containing the number of integer words. The return value is an integer flag denoting success/failure of the operation. This function is advisory only, for use in determining a user's total space requirements; it could be a dummy function in a user-supplied SUNMATRIX module if that information is not of interest.
SUNMatZero	ier = SUNMatZero(A); Performs the operation $A_{ij} = 0$ for all entries of the matrix A . The return value is an integer flag denoting success/failure of the operation.
SUNMatCopy	ier = SUNMatCopy(A,B); Performs the operation $B_{ij} = A_{i,j}$ for all entries of the matrices A and B . The return value is an integer flag denoting success/failure of the operation.
SUNMatScaleAdd	ier = SUNMatScaleAdd(c, A, B); Performs the operation $A = cA + B$. The return value is an integer flag denoting success/failure of the operation.
SUNMatScaleAddI	ier = SUNMatScaleAddI(c, A); Performs the operation $A = cA + I$. The return value is an integer flag denoting success/failure of the operation.
SUNMatMatvec	ier = SUNMatMatvec(A, x, y); Performs the matrix-vector product operation, $y = Ax$. It should only be called with vectors x and y that are compatible with the matrix A – both in storage type and dimensions. The return value is an integer flag denoting success/failure of the operation.

We note that not all SUNMATRIX types are compatible with all NVECTOR types provided with SUNDIALS. This is primarily due to the need for compatibility within the SUNMatMatvec routine; however, compatibility between SUNMATRIX and NVECTOR implementations is more crucial when considering their interaction within SUNLINSOL objects, as will be described in more detail in Chapter 8. More specifically, in Table 7.3 we show the matrix interfaces available as SUNMATRIX modules, and the compatible vector implementations.

Table 7.3: SUNDIALS matrix interfaces and vector implementations that can be used for each.

7.1 The SUNMatrix_Dense implementation

The dense implementation of the SUNMATRIX module provided with SUNDIALS, SUNMATRIX_DENSE, defines the *content* field of SUNMatrix to be the following structure:

```
struct _SUNMatrixContent_Dense {
   sunindextype M;
   sunindextype N;
   realtype *data;
   sunindextype ldata;
   realtype **cols;
};
```

These entries of the *content* field contain the following information:

M - number of rows

N - number of columns

data - pointer to a contiguous block of realtype variables. The elements of the dense matrix are stored columnwise, i.e. the (i,j)-th element of a dense SUNMATRIX A (with $0 \le i < M$ and $0 \le j < N$) may be accessed via data[j*M+i].

ldata - length of the data array $(= M \cdot N)$.

cols - array of pointers. cols[j] points to the first element of the j-th column of the matrix in the array data. The (i,j)-th element of a dense SUNMATRIX A (with $0 \le i < M$ and $0 \le j < N$) may be accessed via cols[j][i].

The header file to include when using this module is sunmatrix/sunmatrix_dense.h. The SUNMATRIX_DENSE module is accessible from all SUNDIALS solvers without linking to the libsundials_sunmatrixdense module library.

The following macros are provided to access the content of a SUNMATRIX_DENSE matrix. The prefix SM_{-} in the names denotes that these macros are for SUNMatrix implementations, and the suffix D denotes that these are specific to the dense version.

• SM_CONTENT_D

This macro gives access to the contents of the dense SUNMatrix.

The assignment $A_cont = SM_CONTENT_D(A)$ sets A_cont to be a pointer to the dense SUNMatrix content structure.

Implementation:

```
#define SM_CONTENT_D(A) ( (SUNMatrixContent_Dense)(A->content) )
```

• SM_ROWS_D, SM_COLUMNS_D, and SM_LDATA_D

These macros give individual access to various lengths relevant to the content of a dense SUNMatrix.

These may be used either to retrieve or to set these values. For example, the assignment A_rows = SM_ROWS_D(A) sets A_rows to be the number of rows in the matrix A. Similarly, the assignment SM_COLUMNS_D(A) = A_cols sets the number of columns in A to equal A_cols.

Implementation:

• SM_DATA_D and SM_COLS_D

These macros give access to the data and cols pointers for the matrix entries.

The assignment A_data = SM_DATA_D(A) sets A_data to be a pointer to the first component of the data array for the dense SUNMatrix A. The assignment SM_DATA_D(A) = A_data sets the data array of A to be A_data by storing the pointer A_data.

Similarly, the assignment $A_cols = SM_COLS_D(A)$ sets A_cols to be a pointer to the array of column pointers for the dense SUNMatrix A. The assignment $SM_COLS_D(A) = A_cols$ sets the column pointer array of A to be A_cols by storing the pointer A_cols .

Implementation:

```
#define SM_DATA_D(A) ( SM_CONTENT_D(A)->data )
#define SM_COLS_D(A) ( SM_CONTENT_D(A)->cols )
```

SM_COLUMN_D and SM_ELEMENT_D

These macros give access to the individual columns and entries of the data array of a dense SUNMatrix.

The assignment col_j = SM_COLUMN_D(A,j) sets col_j to be a pointer to the first entry of the j-th column of the M \times N dense matrix A (with $0 \le j < N$). The type of the expression SM_COLUMN_D(A,j) is realtype *. The pointer returned by the call SM_COLUMN_D(A,j) can be treated as an array which is indexed from 0 to M - 1.

The assignments SM_ELEMENT_D(A,i,j) = a_ij and a_ij = SM_ELEMENT_D(A,i,j) reference the (i,j)-th element of the M × N dense matrix A (with $0 \le i < M$ and $0 \le j < N$).

Implementation:

```
#define SM_COLUMN_D(A,j) ( (SM_CONTENT_D(A)->cols)[j] )
#define SM_ELEMENT_D(A,i,j) ( (SM_CONTENT_D(A)->cols)[j][i] )
```

The SUNMATRIX_DENSE module defines dense implementations of all matrix operations listed in Table 7.2. Their names are obtained from those in Table 7.2 by appending the suffix _Dense (e.g. SUNMatCopy_Dense). The module SUNMATRIX_DENSE provides the following additional user-callable routines:

• SUNDenseMatrix

This constructor function creates and allocates memory for a dense SUNMatrix. Its arguments are the number of rows, M, and columns, N, for the dense matrix.

```
SUNMatrix SUNDenseMatrix(sunindextype M, sunindextype N);
```

• SUNDenseMatrix_Print

This function prints the content of a dense SUNMatrix to the output stream specified by outfile. Note: stdout or stderr may be used as arguments for outfile to print directly to standard output or standard error, respectively.

```
void SUNDenseMatrix_Print(SUNMatrix A, FILE* outfile);
```

• SUNDenseMatrix_Rows

This function returns the number of rows in the dense SUNMatrix. sunindextype SUNDenseMatrix_Rows(SUNMatrix A);

• SUNDenseMatrix_Columns

This function returns the number of columns in the dense SUNMatrix. sunindextype SUNDenseMatrix_Columns(SUNMatrix A);

• SUNDenseMatrix_LData

This function returns the length of the data array for the dense SUNMatrix. sunindextype SUNDenseMatrix_LData(SUNMatrix A);

• SUNDenseMatrix_Data

This function returns a pointer to the data array for the dense SUNMatrix. realtype* SUNDenseMatrix_Data(SUNMatrix A);

• SUNDenseMatrix_Cols

This function returns a pointer to the cols array for the dense SUNMatrix. realtype** SUNDenseMatrix_Cols(SUNMatrix A);

• SUNDenseMatrix_Column

This function returns a pointer to the first entry of the jth column of the dense SUNMatrix. The resulting pointer should be indexed over the range 0 to M-1.

```
realtype* SUNDenseMatrix_Column(SUNMatrix A, sunindextype j);
```

Notes

- When looping over the components of a dense SUNMatrix A, the most efficient approaches are to:
 - First obtain the component array via A_data = SM_DATA_D(A) or
 A_data = SUNDenseMatrix_Data(A) and then access A_data[i] within the loop.
 - First obtain the array of column pointers via A_cols = SM_COLS_D(A) or A_cols = SUNDenseMatrix_Cols(A), and then access A_cols[j][i] within the loop.
 - Within a loop over the columns, access the column pointer via
 A_colj = SUNDenseMatrix_Column(A,j) and then to access the entries within that column using A_colj[i] within the loop.

All three of these are more efficient than using SM_ELEMENT_D(A,i,j) within a double loop.

• Within the SUNMatMatvec_Dense routine, internal consistency checks are performed to ensure that the matrix is called with consistent NVECTOR implementations. These are currently limited to: NVECTOR_SERIAL, NVECTOR_OPENMP, and NVECTOR_PTHREADS. As additional compatible vector implementations are added to SUNDIALS, these will be included within this compatibility check.

For solvers that include a Fortran interface module, the SUNMATRIX_DENSE module also includes the Fortran-callable function FSUNDenseMatInit(code, M, N, ier) to initialize this SUNMATRIX_DENSE module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); M and N are the corresponding dense matrix construction arguments (declared to match C type long int); and ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNDenseMassMatInit(M, N, ier) initializes this SUNMATRIX_DENSE module for storing the mass matrix.

7.2 The SUNMatrix_Band implementation

The banded implementation of the SUNMATRIX module provided with SUNDIALS, SUNMATRIX_BAND, defines the *content* field of SUNMatrix to be the following structure:

```
struct _SUNMatrixContent_Band {
   sunindextype M;
   sunindextype N;
   sunindextype mu;
   sunindextype ml;
   sunindextype s_mu;
   sunindextype ldim;
   realtype *data;
   sunindextype ldata;
   realtype **cols;
};
```

A diagram of the underlying data representation in a banded matrix is shown in Figure 7.1. A more complete description of the parts of this *content* field is given below:

```
M - number of rows \label{eq:N-mu} \textbf{N} \text{ - number of columns } (\textbf{N} = \textbf{M}) \label{eq:Mu-mu-mu} \textbf{mu} \text{ - upper half-bandwidth, } 0 \leq \textbf{mu} < \textbf{N} \label{eq:Mu-number of rows} \textbf{ml} \text{ - lower half-bandwidth, } 0 \leq \textbf{ml} < \textbf{N}
```

s_mu - storage upper bandwidth, mu ≤ s_mu < N. The LU decomposition routines in the associated SUNLINSOL_BAND and SUNLINSOL_LAPACKBAND modules write the LU factors into the storage for A. The upper triangular factor U, however, may have an upper bandwidth as big as min(N-1,mu+ml) because of partial pivoting. The s_mu field holds the upper half-bandwidth allocated for A.</p>

```
ldim - leading dimension (ldim \ge s_mu+ml+1)
```

data - pointer to a contiguous block of realtype variables. The elements of the banded matrix are stored columnwise (i.e. columns are stored one on top of the other in memory). Only elements within the specified half-bandwidths are stored. data is a pointer to ldata contiguous locations which hold the elements within the band of A.

```
ldata - length of the data array (= ldim \cdot N)
```

cols - array of pointers. cols[j] is a pointer to the uppermost element within the band in the j-th column. This pointer may be treated as an array indexed from s_mu-mu (to access the uppermost element within the band in the j-th column) to s_mu+ml (to access the lowest element within the band in the j-th column). Indices from 0 to $s_mu-mu-1$ give access to extra storage elements required by the LU decomposition function. Finally, $cols[j][i-j+s_mu]$ is the (i,j)-th element with $j-mu \le i \le j+ml$.

The header file to include when using this module is sunmatrix/sunmatrix_band.h. The SUNMATRIX_BAND module is accessible from all SUNDIALS solvers without linking to the libsundials_sunmatrixband module library.

The following macros are provided to access the content of a SUNMATRIX_BAND matrix. The prefix SM_ in the names denotes that these macros are for *SUNMatrix* implementations, and the suffix _B denotes that these are specific to the *banded* version.

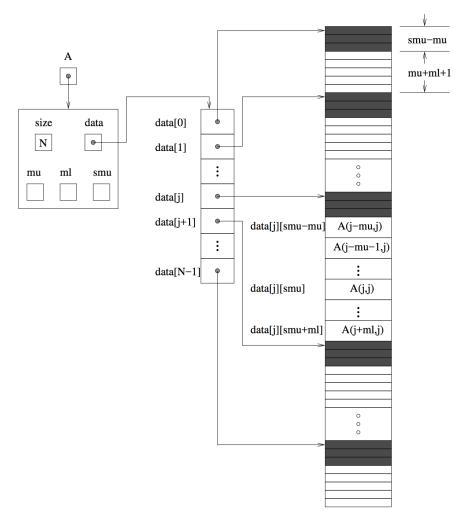

Figure 7.1: Diagram of the storage for the SUNMATRIX_BAND module. Here A is an N \times N band matrix with upper and lower half-bandwidths mu and ml, respectively. The rows and columns of A are numbered from 0 to N - 1 and the (i,j)-th element of A is denoted A(i,j). The greyed out areas of the underlying component storage are used by the associated SUNLINSOL_BAND linear solver.

• SM_CONTENT_B

This routine gives access to the contents of the banded SUNMatrix.

The assignment A_cont = SM_CONTENT_B(A) sets A_cont to be a pointer to the banded SUNMatrix content structure.

Implementation:

```
#define SM_CONTENT_B(A) ((SUNMatrixContent_Band)(A->content) )
```

SM_ROWS_B, SM_COLUMNS_B, SM_UBAND_B, SM_LBAND_B, SM_SUBAND_B, SM_LDIM_B, and SM_LDATA_B
 These macros give individual access to various lengths relevant to the content of a banded SUNMatrix.

These may be used either to retrieve or to set these values. For example, the assignment A_rows = SM_ROWS_B(A) sets A_rows to be the number of rows in the matrix A. Similarly, the assignment SM_COLUMNS_B(A) = A_cols sets the number of columns in A to equal A_cols.

Implementation:

```
#define SM_ROWS_B(A) ( SM_CONTENT_B(A)->M )
#define SM_COLUMNS_B(A) ( SM_CONTENT_B(A)->N )
#define SM_UBAND_B(A) ( SM_CONTENT_B(A)->mu )
#define SM_LBAND_B(A) ( SM_CONTENT_B(A)->ml )
#define SM_SUBAND_B(A) ( SM_CONTENT_B(A)->s_mu )
#define SM_LDIM_B(A) ( SM_CONTENT_B(A)->ldim )
#define SM_LDATA_B(A) ( SM_CONTENT_B(A)->ldata )
```

• SM_DATA_B and SM_COLS_B

These macros give access to the data and cols pointers for the matrix entries.

The assignment A_data = SM_DATA_B(A) sets A_data to be a pointer to the first component of the data array for the banded SUNMatrix A. The assignment SM_DATA_B(A) = A_data sets the data array of A to be A_data by storing the pointer A_data.

Similarly, the assignment A_cols = SM_COLS_B(A) sets A_cols to be a pointer to the array of column pointers for the banded SUNMatrix A. The assignment SM_COLS_B(A) = A_cols sets the column pointer array of A to be A_cols by storing the pointer A_cols.

Implementation:

```
#define SM_DATA_B(A) ( SM_CONTENT_B(A)->data )
#define SM_COLS_B(A) ( SM_CONTENT_B(A)->cols )
```

• SM_COLUMN_B, SM_COLUMN_ELEMENT_B, and SM_ELEMENT_B

These macros give access to the individual columns and entries of the data array of a banded SUNMatrix.

The assignments SM_ELEMENT_B(A,i,j) = a_ij and a_ij = SM_ELEMENT_B(A,i,j) reference the (i,j)-th element of the N × N band matrix A, where $0 \le i, j \le N-1$. The location (i,j) should further satisfy $j-mu \le i \le j+ml$.

The assignment $col_j = SM_COLUMN_B(A,j)$ sets col_j to be a pointer to the diagonal element of the j-th column of the N × N band matrix A, $0 \le j \le N-1$. The type of the expression $SM_COLUMN_B(A,j)$ is realtype *. The pointer returned by the call $SM_COLUMN_B(A,j)$ can be treated as an array which is indexed from -mu to ml.

The assignments SM_COLUMN_ELEMENT_B(col_j,i,j) = a_ij and

a_ij = SM_COLUMN_ELEMENT_B(col_j,i,j) reference the (i,j)-th entry of the band matrix A when used in conjunction with SM_COLUMN_B to reference the j-th column through col_j. The index (i,j) should satisfy $j-mu \le i \le j+ml$.

Implementation:

The SUNMATRIX_BAND module defines banded implementations of all matrix operations listed in Table 7.2. Their names are obtained from those in Table 7.2 by appending the suffix _Band (e.g. SUNMatCopy_Band). The module SUNMATRIX_BAND provides the following additional user-callable routines:

• SUNBandMatrix

This constructor function creates and allocates memory for a banded SUNMatrix. Its arguments are the matrix size, N, the upper and lower half-bandwidths of the matrix, mu and ml, and the stored upper bandwidth, smu. When creating a band SUNMatrix, this value should be

- at least min(N-1,mu+ml) if the matrix will be used by the SUNLINSOL_BAND module;
- exactly equal to mu+ml if the matrix will be used by the SUNLINSOL_LAPACKBAND module;
- at least mu if used in some other manner.

```
SUNMatrix SUNBandMatrix(sunindextype N, sunindextype mu, sunindextype ml, sunindextype smu);
```

• SUNBandMatrix_Print

This function prints the content of a banded SUNMatrix to the output stream specified by outfile. Note: stdout or stderr may be used as arguments for outfile to print directly to standard output or standard error, respectively.

```
void SUNBandMatrix_Print(SUNMatrix A, FILE* outfile);
```

• SUNBandMatrix_Rows

This function returns the number of rows in the banded SUNMatrix. sunindextype SUNBandMatrix_Rows(SUNMatrix A);

• SUNBandMatrix_Columns

This function returns the number of columns in the banded SUNMatrix. sunindextype SUNBandMatrix_Columns(SUNMatrix A);

• SUNBandMatrix_LowerBandwidth

This function returns the lower half-bandwidth of the banded SUNMatrix. sunindextype SUNBandMatrix_LowerBandwidth(SUNMatrix A);

• SUNBandMatrix_UpperBandwidth

This function returns the upper half-bandwidth of the banded SUNMatrix. sunindextype SUNBandMatrix_UpperBandwidth(SUNMatrix A);

• SUNBandMatrix_StoredUpperBandwidth

This function returns the stored upper half-bandwidth of the banded SUNMatrix. sunindextype SUNBandMatrix_StoredUpperBandwidth(SUNMatrix A);

• SUNBandMatrix_LDim

This function returns the length of the leading dimension of the banded SUNMatrix.sunindextype SUNBandMatrix_LDim(SUNMatrix A);

• SUNBandMatrix_Data

This function returns a pointer to the data array for the banded SUNMatrix.realtype* SUNBandMatrix_Data(SUNMatrix A);

• SUNBandMatrix_Cols

This function returns a pointer to the cols array for the banded SUNMatrix.

```
realtype** SUNBandMatrix_Cols(SUNMatrix A);
```

• SUNBandMatrix_Column

This function returns a pointer to the diagonal entry of the j-th column of the banded SUNMatrix. The resulting pointer should be indexed over the range —mu to ml.

```
realtype* SUNBandMatrix_Column(SUNMatrix A, sunindextype j);
```

Notes

- When looping over the components of a banded SUNMatrix A, the most efficient approaches are to:
 - First obtain the component array via A_data = SM_DATA_B(A) or A_data = SUNBandMatrix_Data(A) and then access A_data[i] within the loop.
 - First obtain the array of column pointers via A_cols = SM_COLS_B(A) or A_cols = SUNBandMatrix_Cols(A), and then access A_cols[j][i] within the loop.
 - Within a loop over the columns, access the column pointer via
 A_colj = SUNBandMatrix_Column(A,j) and then to access the entries within that column using SM_COLUMN_ELEMENT_B(A_colj,i,j).

All three of these are more efficient than using SM_ELEMENT_B(A,i,j) within a double loop.

Within the SUNMatMatvec_Band routine, internal consistency checks are performed to ensure
that the matrix is called with consistent NVECTOR implementations. These are currently limited
to: NVECTOR_SERIAL, NVECTOR_OPENMP, and NVECTOR_PTHREADS. As additional compatible
vector implementations are added to SUNDIALS, these will be included within this compatibility
check.

For solvers that include a Fortran interface module, the SUNMATRIX_BAND module also includes the Fortran-callable function FSUNBandMatInit(code, N, mu, ml, smu, ier) to initialize this SUNMATRIX_BAND module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); N, mu, ml and smu are the corresponding band matrix construction arguments (declared to match C type long int); and ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNBandMassMatInit(N, mu, ml, smu, ier) initializes this SUNMATRIX_BAND module for storing the mass matrix.

7.3 The SUNMatrix_Sparse implementation

The sparse implementation of the Sunmatrix module provided with Sundials, Sunmatrix_sparse, is designed to work with either *compressed-sparse-column* (CSC) or *compressed-sparse-row* (CSR) sparse matrix formats. To this end, it defines the *content* field of Sunmatrix to be the following structure:

```
struct _SUNMatrixContent_Sparse {
  sunindextype M;
  sunindextype N;
  sunindextype NNZ;
  sunindextype NP;
  realtype *data;
  int sparsetype;
  sunindextype *indexvals;
  sunindextype *indexptrs;
  /* CSC indices */
  sunindextype **rowvals;
  sunindextype **colptrs;
  /* CSR indices */
  sunindextype **colvals;
  sunindextype **rowptrs;
};
```

A diagram of the underlying data representation for a CSC matrix is shown in Figure 7.2 (the CSR format is similar). A more complete description of the parts of this *content* field is given below:

M - number of rows

 ${f N}$ - number of columns

NNZ - maximum number of nonzero entries in the matrix (allocated length of data and indexvals arrays)

NP - number of index pointers (e.g. number of column pointers for CSC matrix). For CSC matrices NP = N, and for CSR matrices NP = M. This value is set automatically based the input for sparsetype.

data - pointer to a contiguous block of realtype variables (of length NNZ), containing the values of the nonzero entries in the matrix

sparsetype - type of the sparse matrix (CSC_MAT or CSR_MAT)

indexvals - pointer to a contiguous block of int variables (of length NNZ), containing the row indices (if CSC) or column indices (if CSR) of each nonzero matrix entry held in data

indexptrs - pointer to a contiguous block of int variables (of length NP+1). For CSC matrices each entry provides the index of the first column entry into the data and indexvals arrays, e.g. if indexptr[3]=7, then the first nonzero entry in the fourth column of the matrix is located in data[7], and is located in row indexvals[7] of the matrix. The last entry contains the total number of nonzero values in the matrix and hence points one past the end of the active data in the data and indexvals arrays. For CSR matrices, each entry provides the index of the first row entry into the data and indexvals arrays.

The following pointers are added to the SlsMat type for user convenience, to provide a more intuitive interface to the CSC and CSR sparse matrix data structures. They are set automatically when creating a sparse SUNMATRIX, based on the sparse matrix storage type.

rowvals - pointer to indexvals when sparsetype is CSC_MAT, otherwise set to NULL.

colptrs - pointer to indexptrs when sparsetype is CSC_MAT, otherwise set to NULL.

colvals - pointer to indexvals when sparsetype is CSR_MAT, otherwise set to NULL.

rowptrs - pointer to indexptrs when sparsetype is CSR_MAT, otherwise set to NULL.

For example, the 5×4 CSC matrix

$$\left[\begin{array}{cccc} 0 & 3 & 1 & 0 \\ 3 & 0 & 0 & 2 \\ 0 & 7 & 0 & 0 \\ 1 & 0 & 0 & 9 \\ 0 & 0 & 0 & 5 \end{array}\right]$$

could be stored in this structure as either

```
M = 5;
 N = 4;
  NNZ = 8;
  NP = N;
  data = \{3.0, 1.0, 3.0, 7.0, 1.0, 2.0, 9.0, 5.0\};
  sparsetype = CSC_MAT;
  indexvals = \{1, 3, 0, 2, 0, 1, 3, 4\};
  indexptrs = \{0, 2, 4, 5, 8\};
or
 M = 5;
  N = 4;
  NNZ = 10;
  NP = N;
  data = \{3.0, 1.0, 3.0, 7.0, 1.0, 2.0, 9.0, 5.0, *, *\};
  sparsetype = CSC_MAT;
  indexvals = \{1, 3, 0, 2, 0, 1, 3, 4, *, *\};
  indexptrs = \{0, 2, 4, 5, 8\};
```

where the first has no unused space, and the second has additional storage (the entries marked with * may contain any values). Note in both cases that the final value in indexptrs is 8, indicating the total number of nonzero entries in the matrix.

Similarly, in CSR format, the same matrix could be stored as

```
M = 5;
N = 4;
NNZ = 8;
NP = N;
data = {3.0, 1.0, 3.0, 2.0, 7.0, 1.0, 9.0, 5.0};
sparsetype = CSR_MAT;
indexvals = {1, 2, 0, 3, 1, 0, 3, 3};
indexptrs = {0, 2, 4, 5, 7, 8};
```

The header file to include when using this module is sunmatrix/sunmatrix_sparse.h. The SUNMATRIX_SPARSE module is accessible from all SUNDIALS solvers without linking to the libsundials_sunmatrixsparse module library.

The following macros are provided to access the content of a SUNMATRIX_SPARSE matrix. The prefix SM_ in the names denotes that these macros are for *SUNMatrix* implementations, and the suffix _S denotes that these are specific to the *sparse* version.

• SM_CONTENT_S

This routine gives access to the contents of the sparse SUNMatrix.

The assignment $A_cont = SM_CONTENT_S(A)$ sets A_cont to be a pointer to the sparse SUNMatrix content structure.

Implementation:

```
#define SM_CONTENT_S(A) ( (SUNMatrixContent_Sparse) (A->content) )
```

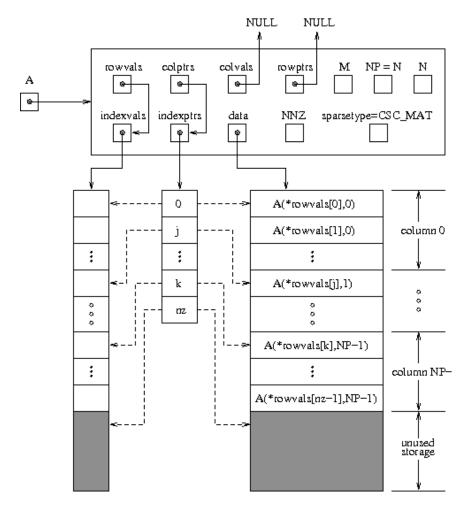

Figure 7.2: Diagram of the storage for a compressed-sparse-column matrix. Here A is an $M \times N$ sparse matrix with storage for up to NNZ nonzero entries (the allocated length of both data and indexvals). The entries in indexvals may assume values from 0 to M-1, corresponding to the row index (zero-based) of each nonzero value. The entries in data contain the values of the nonzero entries, with the row i, column j entry of A (again, zero-based) denoted as A(i,j). The indexptrs array contains N+1 entries; the first N denote the starting index of each column within the indexvals and data arrays, while the final entry points one past the final nonzero entry. Here, although NNZ values are allocated, only nz are actually filled in; the greyed-out portions of data and indexvals indicate extra allocated space.

• SM_ROWS_S, SM_COLUMNS_S, SM_NNZ_S, SM_NP_S, and SM_SPARSETYPE_S

These macros give individual access to various lengths relevant to the content of a sparse SUNMatrix.

These may be used either to retrieve or to set these values. For example, the assignment A_rows = SM_ROWS_S(A) sets A_rows to be the number of rows in the matrix A. Similarly, the assignment SM_COLUMNS_S(A) = A_cols sets the number of columns in A to equal A_cols.

Implementation:

```
#define SM_ROWS_S(A) ( SM_CONTENT_S(A)->M )
#define SM_COLUMNS_S(A) ( SM_CONTENT_S(A)->N )
#define SM_NNZ_S(A) ( SM_CONTENT_S(A)->NNZ )
#define SM_NP_S(A) ( SM_CONTENT_S(A)->NP )
#define SM_SPARSETYPE_S(A) ( SM_CONTENT_S(A)->sparsetype )
```

• SM_DATA_S, SM_INDEXVALS_S, and SM_INDEXPTRS_S

These macros give access to the data and index arrays for the matrix entries.

The assignment A_data = SM_DATA_S(A) sets A_data to be a pointer to the first component of the data array for the sparse SUNMatrix A. The assignment SM_DATA_S(A) = A_data sets the data array of A to be A_data by storing the pointer A_data.

Similarly, the assignment A_indexvals = SM_INDEXVALS_S(A) sets A_indexvals to be a pointer to the array of index values (i.e. row indices for a CSC matrix, or column indices for a CSR matrix) for the sparse SUNMatrix A. The assignment A_indexptrs = SM_INDEXPTRS_S(A) sets A_indexptrs to be a pointer to the array of index pointers (i.e. the starting indices in the data/indexvals arrays for each row or column in CSR or CSC formats, respectively).

Implementation:

```
#define SM_DATA_S(A) ( SM_CONTENT_S(A)->data )
#define SM_INDEXVALS_S(A) ( SM_CONTENT_S(A)->indexvals )
#define SM_INDEXPTRS_S(A) ( SM_CONTENT_S(A)->indexptrs )
```

The SUNMATRIX_SPARSE module defines sparse implementations of all matrix operations listed in Table 7.2. Their names are obtained from those in Table 7.2 by appending the suffix _Sparse (e.g. SUNMatCopy_Sparse). The module SUNMATRIX_SPARSE provides the following additional user-callable routines:

• SUNSparseMatrix

This function creates and allocates memory for a sparse SUNMatrix. Its arguments are the number of rows and columns of the matrix, M and N, the maximum number of nonzeros to be stored in the matrix, NNZ, and a flag sparsetype indicating whether to use CSR or CSC format (valid arguments are CSR_MAT or CSC_MAT).

```
SUNMatrix SUNSparseMatrix(sunindextype M, sunindextype N, sunindextype NNZ, int sparsetype);
```

• SUNSparseFromDenseMatrix

This function creates a new sparse matrix from an existing dense matrix by copying all values with magnitude larger than droptol into the sparse matrix structure.

Requirements:

- A must have type SUNMATRIX_DENSE;

- droptol must be non-negative;
- sparsetype must be either CSC_MAT or CSR_MAT.

The function returns NULL if any requirements are violated, or if the matrix storage request cannot be satisfied.

• SUNSparseFromBandMatrix

This function creates a new sparse matrix from an existing band matrix by copying all values with magnitude larger than droptol into the sparse matrix structure.

Requirements:

- A must have type SUNMATRIX_BAND;
- droptol must be non-negative;
- sparsetype must be either CSC_MAT or CSR_MAT.

The function returns NULL if any requirements are violated, or if the matrix storage request cannot be satisfied.

• SUNSparseMatrix_Realloc

This function reallocates internal storage arrays in a sparse matrix so that the resulting sparse matrix has no wasted space (i.e. the space allocated for nonzero entries equals the actual number of nonzeros, indexptrs[NP]). Returns 0 on success and 1 on failure (e.g. if the input matrix is not sparse).

int SUNSparseMatrix_Realloc(SUNMatrix A);

• SUNSparseMatrix_Reallocate

This function reallocates internal storage arrays in a sparse matrix so that the resulting sparse matrix has storage for a specified number of nonzeros. Returns 0 on success and 1 on failure (e.g. if the input matrix is not sparse or if NNZ is negative).

int SUNSparseMatrix_Reallocate(SUNMatrix A, sunindextype NNZ);

• SUNSparseMatrix_Print

This function prints the content of a sparse SUNMatrix to the output stream specified by outfile. Note: stdout or stderr may be used as arguments for outfile to print directly to standard output or standard error, respectively.

void SUNSparseMatrix_Print(SUNMatrix A, FILE* outfile);

• SUNSparseMatrix_Rows

This function returns the number of rows in the sparse SUNMatrix.

sunindextype SUNSparseMatrix_Rows(SUNMatrix A);

• SUNSparseMatrix_Columns

This function returns the number of columns in the sparse SUNMatrix.

sunindextype SUNSparseMatrix_Columns(SUNMatrix A);

• SUNSparseMatrix_NNZ

This function returns the number of entries allocated for nonzero storage for the sparse matrix SUNMatrix.

sunindextype SUNSparseMatrix_NNZ(SUNMatrix A);

• SUNSparseMatrix_NP

This function returns the number of columns/rows for the sparse SUNMatrix, depending on whether the matrix uses CSC/CSR format, respectively. The indexptrs array has NP+1 entries. sunindextype SUNSparseMatrix_NP(SUNMatrix A);

• SUNSparseMatrix_SparseType

This function returns the storage type (CSR_MAT or CSC_MAT) for the sparse SUNMatrix. int SUNSparseMatrix_SparseType(SUNMatrix A);

• SUNSparseMatrix_Data

This function returns a pointer to the data array for the sparse SUNMatrix. realtype* SUNSparseMatrix_Data(SUNMatrix A);

• SUNSparseMatrix_IndexValues

This function returns a pointer to index value array for the sparse SUNMatrix: for CSR format this is the column index for each nonzero entry, for CSC format this is the row index for each nonzero entry.

sunindextype* SUNSparseMatrix_IndexValues(SUNMatrix A);

• SUNSparseMatrix_IndexPointers

This function returns a pointer to the index pointer array for the sparse SUNMatrix: for CSR format this is the location of the first entry of each row in the data and indexvalues arrays, for CSC format this is the location of the first entry of each column.

```
sunindextype* SUNSparseMatrix_IndexPointers(SUNMatrix A);
```

Within the SUNMatMatvec_Sparse routine, internal consistency checks are performed to ensure that the matrix is called with consistent NVECTOR implementations. These are currently limited to: NVECTOR_SERIAL, NVECTOR_OPENMP, and NVECTOR_PTHREADS. As additional compatible vector implementations are added to SUNDIALS, these will be included within this compatibility check.

For solvers that include a Fortran interface module, the SUNMATRIX_SPARSE module also includes the Fortran-callable function FSUNSparseMatInit(code, M, N, NNZ, sparsetype, ier) to initialize this SUNMATRIX_SPARSE module for a given SUNDIALS solver. Here code is an integer input for the solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); M, N and NNZ are the corresponding sparse matrix construction arguments (declared to match C type long int); sparsetype is an integer flag indicating the sparse storage type (0 for CSC, 1 for CSR); and ier is an error return flag equal to 0 for success and -1 for failure. Each of code, sparsetype and ier are declared so as to match C type int. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNSparseMassMatInit(M, N, NNZ, sparsetype, ier) initializes this SUNMATRIX_SPARSE module for storing the mass matrix.

7.4 SUNMatrix Examples

There are SUNMatrix examples that may be installed for each implementation: dense, banded, and sparse. Each implementation makes use of the functions in test_sunmatrix.c. These example functions show simple usage of the SUNMatrix family of functions. The inputs to the examples depend on the matrix type, and are output to stdout if the example is run without the appropriate number of command-line arguments.

The following is a list of the example functions in test_sunmatrix.c:

- Test_SUNMatGetID: Verifies the returned matrix ID against the value that should be returned.
- Test_SUNMatClone: Creates clone of an existing matrix, copies the data, and checks that their values match.
- Test_SUNMatZero: Zeros out an existing matrix and checks that each entry equals 0.0.
- Test_SUNMatCopy: Clones an input matrix, copies its data to a clone, and verifies that all values match.
- Test_SUNMatScaleAdd: Given an input matrix A and an input identity matrix I, this test clones and copies A to a new matrix B, computes B = -B + B, and verifies that the resulting matrix entries equal 0.0. Additionally, if the matrix is square, this test clones and copies A to a new matrix D, clones and copies I to a new matrix C, computes D = D + I and C = C + A using SUNMatScaleAdd, and then verifies that C == D.
- Test_SUNMatScaleAddI: Given an input matrix A and an input identity matrix I, this clones and copies I to a new matrix B, computes B = -B + I using SUNMatScaleAddI, and verifies that the resulting matrix entries equal 0.0.
- Test_SUNMatMatvec Given an input matrix A and input vectors x and y such that y = Ax, this test has different behavior depending on whether A is square. If it is square, it clones and copies A to a new matrix B, computes B = 3B + I using SUNMatScaleAddI, clones y to new vectors w and z, computes z = Bx using SUNMatMatvec, computes w = 3y + x using N_VLinearSum, and verifies that w == z. If A is not square, it just clones y to a new vector z, computes z = Ax using SUNMatMatvec, and verifies that y == z.
- Test_SUNMatSpace verifies that SUNMatSpace can be called, and outputs the results to stdout.

7.5 SUNMatrix functions used by CVODE

In Table 7.4, we list the matrix functions in the SUNMATRIX module used within the CVODE package. The table also shows, for each function, which of the code modules uses the function. Neither the main CVODE integrator or the CVSPILS interface call SUNMATRIX functions directly, so the table columns are specific to the CVDLS direct solver interface and the CVBANDPRE and CVBBDPRE preconditioner modules.

At this point, we should emphasize that the CVODE user does not need to know anything about the usage of matrix functions by the CVODE code modules in order to use CVODE. The information is presented as an implementation detail for the interested reader.

	CVDLS	CVBANDPRE	CVBBDPRE
SUNMatGetID	√		
SUNMatClone	√		
SUNMatDestroy	√	√	√
SUNMatZero	√	√	√
SUNMatCopy	√	√	√
SUNMatScaleAddI	√	√	√
SUNMatSpace	†	†	†

Table 7.4: List of matrix functions usage by CVODE code modules

The matrix functions listed in Table 7.2 with a † symbol are optionally used, in that these are only called if they are implemented in the SUNMATRIX module that is being used (i.e. their function pointers are non-NULL). The matrix functions listed in Table 7.2 that are *not* used by CVODE are: SUNMatScaleAdd and SUNMatMatvec. Therefore a user-supplied SUNMATRIX module for CVODE could omit these functions.

Chapter 8

Description of the SUNLinearSolver module

For problems that involve the solution of linear systems of equations, the SUNDIALS solvers operate using generic linear solver modules (of type SUNLinearSolver), through a set of operations defined by the particular SUNLINSOL implementation. These work in coordination with the SUNDIALS generic NVECTOR and SUNMATRIX modules to provide a set of compatible data structures and solvers for the solution of linear systems using direct or iterative methods. Moreover, users can provide their own specific SUNLINSOL implementation to each SUNDIALS solver, particularly in cases where they provide their own NVECTOR and/or SUNMATRIX modules, and the customized linear solver leverages these additional data structures to create highly efficient and/or scalable solvers for their particular problem. Additionally, SUNDIALS provides native implementations SUNLINSOL modules, as well as SUNLINSOL modules that interface between SUNDIALS and external linear solver libraries.

The various SUNDIALS solvers have been designed to specifically leverage the use of either direct linear solvers or scaled, preconditioned, iterative linear solvers, through their "Dls" and "Spils" interfaces, respectively. Additionally, SUNDIALS solvers can make use of user-supplied custom linear solvers, whether these are problem-specific or come from external solver libraries.

For iterative (and possibly custom) linear solvers, the SUNDIALS solvers leverage scaling and preconditioning, as applicable, to balance error between solution components and to accelerate convergence of the linear solver. To this end, instead of solving the linear system Ax = b directly, we apply the underlying iterative algorithm to the transformed system

$$\tilde{A}\tilde{x} = \tilde{b} \tag{8.1}$$

where

$$\tilde{A} = S_1 P_1^{-1} A P_2^{-1} S_2^{-1},$$

$$\tilde{b} = S_1 P_1^{-1} b,$$

$$\tilde{x} = S_2 P_2 x,$$
(8.2)

and where

- P_1 is the left preconditioner,
- P_2 is the right preconditioner,
- S_1 is a diagonal matrix of scale factors for $P_1^{-1}b$,
- S_2 is a diagonal matrix of scale factors for P_2x .

The SUNDIALS solvers request that iterative linear solvers stop based on the 2-norm of the scaled preconditioned residual meeting a prescribed tolerance

$$\left\| \tilde{b} - \tilde{A}\tilde{x} \right\|_{2} < \text{tol.}$$

We note that not all of the iterative linear solvers implemented in SUNDIALS support the full range of the above options. Similarly, some of the SUNDIALS integrators only utilize a subset of these options. Exceptions to the operators shown above are described in the documentation for each SUNLINSOL implementation, or for each SUNDIALS solver "Spils" interface.

The generic SUNLinearSolver type has been modeled after the object-oriented style of the generic N_Vector type. Specifically, a generic SUNLinearSolver is a pointer to a structure that has an implementation-dependent *content* field containing the description and actual data of the linear solver, and an *ops* field pointing to a structure with generic linear solver operations. The type SUNLinearSolver is defined as

```
typedef struct _generic_SUNLinearSolver *SUNLinearSolver;
struct _generic_SUNLinearSolver {
  void *content;
  struct _generic_SUNLinearSolver_Ops *ops;
};
```

The _generic_SUNLinearSolver_Ops structure is essentially a list of pointers to the various actual linear solver operations, and is defined as

```
struct _generic_SUNLinearSolver_Ops {
  SUNLinearSolver_Type (*gettype)(SUNLinearSolver);
                        (*setatimes)(SUNLinearSolver, void*, ATimesFn);
  int
                        (*setpreconditioner)(SUNLinearSolver, void*,
  int
                                             PSetupFn, PSolveFn);
                        (*setscalingvectors)(SUNLinearSolver,
  int
                                             N_Vector, N_Vector);
                        (*initialize)(SUNLinearSolver);
  int
                        (*setup)(SUNLinearSolver, SUNMatrix);
  int
  int
                        (*solve)(SUNLinearSolver, SUNMatrix, N_Vector,
                                 N_Vector, realtype);
  int
                        (*numiters)(SUNLinearSolver);
                        (*resnorm)(SUNLinearSolver);
  realtype
  long int
                        (*lastflag)(SUNLinearSolver);
  int
                        (*space)(SUNLinearSolver, long int*, long int*);
 N_Vector
                        (*resid)(SUNLinearSolver);
  int
                        (*free)(SUNLinearSolver);
};
```

The generic SUNLINSOL module defines and implements the linear solver operations acting on SUNLinearSolver objects. These routines are in fact only wrappers for the linear solver operations defined by a particular SUNLINSOL implementation, which are accessed through the *ops* field of the SUNLinearSolver structure. To illustrate this point we show below the implementation of a typical linear solver operation from the generic SUNLINSOL module, namely SUNLinSolInitialize, which initializes a SUNLINSOL object for use after it has been created and configured, and returns a flag denoting a successful/failed operation:

```
int SUNLinSolInitialize(SUNLinearSolver S)
{
  return ((int) S->ops->initialize(S));
}
```

Table 8.2 contains a complete list of all linear solver operations defined by the generic SUNLINSOL module. In order to support both direct and iterative linear solver types, the generic SUNLINSOL module defines linear solver routines (or arguments) that may be specific to individual use cases. As such, for each routine we specify its intended use. If a custom SUNLINSOL module is provided, the function pointers for non-required routines may be set to NULL to indicate that they are not provided.

A particular implementation of the SUNLINSOL module must:

Table 8.1: Identifiers associated with linear solver kernels supplied with SUNDIALS.

Linear Solver ID	Solver type	ID Value
SUNLINEARSOLVER_DIRECT	Direct solvers	0
SUNLINEARSOLVER_ITERATIVE	Iterative solvers	1
SUNLINEARSOLVER_CUSTOM	Custom solvers	2

- Specify the *content* field of the SUNLinearSolver object.
- Define and implement a minimal subset of the linear solver operations. See the documentation for each SUNDIALS linear solver interface to determine which SUNLINSOL operations they require. Note that the names of these routines should be unique to that implementation in order to permit using more than one SUNLINSOL module (each with different SUNLinearSolver internal data representations) in the same code.
- Define and implement user-callable constructor and destructor routines to create and free a SUNLinearSolver with the new *content* field and with *ops* pointing to the new linear solver operations.
- Optionally, define and implement additional user-callable routines acting on the newly defined SUNLinearSolver (e.g., routines to set various configuration options for tuning the linear solver to a particular problem).
- Optionally, provide functions as needed for that particular implementation to access different parts in the *content* field of the newly defined SUNLinearSolver object (e.g., routines to return various statistics from the solver).

Each SUNLINSOL implementation included in SUNDIALS has a "type" identifier specified in enumeration and shown in Table 8.1. It is recommended that a user-supplied SUNLINSOL implementation set this identifier based on the SUNDIALS solver interface they intend to use: "Dls" interfaces require the SUNLINEARSOLVER_DIRECT SUNLINSOL objects and "Spils" interfaces require the SUNLINEARSOLVER_ITERATIVE objects.

Table 8.2: Description of the SUNLinearSolver operations

Name	Usage and Description
SUNLinSolGetType	type = SUNLinSolGetType(LS); Returns the type identifier for the linear solver LS. It is used to determine the solver type (direct, iterative, or custom) from the abstract SUNLinearSolver interface. This is used to assess compatibility with SUNDIALS-provided linear solver interfaces. Returned values are given in the Table 8.1.
	continued on next page

Name	Usage and Description
SUNLinSolInitialize	ier = SUNLinSolInitialize(LS); Performs linear solver initialization (assumes that all solver-specific options have been set). This should return zero for a successful call, and a negative value for a failure, ideally returning one of the generic error codes listed in Table 8.4.
SUNLinSolSetup	ier = SUNLinSolSetup(LS, A); Performs any linear solver setup needed, based on an updated system SUNMATRIX A. This may be called frequently (e.g. with a full Newton method) or infrequently (for a modified Newton method), based on the type of integrator and/or nonlinear solver requesting the solves. This should return zero for a successful call, a positive value for a recoverable failure and a negative value for an unrecoverable failure, ideally returning one of the generic error codes listed in Table 8.4.
SUNLinSolSolve	ier = SUNLinSolSolve(LS, A, x, b, tol); Solves a linear system $Ax = b$. This should return zero for a successful call, a positive value for a recoverable failure and a negative value for an unrecoverable failure, ideally returning one of the generic error codes listed in Table 8.4. Direct solvers: can ignore the realtype argument tol. Iterative solvers: can ignore the SUNMATRIX input A since a NULL argument will be passed (these should instead rely on the matrix-vector product function supplied through the routine SUNLinSolSetATimes). These should attempt to solve to the specified realtype tolerance tol in a weighted 2-norm. If the solver does not support scaling then it should just use a 2-norm. Custom solvers: all arguments will be supplied, and if the solver is approximate then it should attempt to solve to the specified realtype tolerance tol in a weighted 2-norm. If the solver does not support scaling then it should just use a 2-norm.
SUNLinSolFree	ier = SUNLinSolFree(LS); Frees memory allocated by the linear solver. This should return zero for a successful call, and a negative value for a failure.
SUNLinSolSetATimes	ier = SUNLinSolSetATimes(LS, A_data, ATimes); (Iterative/Custom linear solvers only) Provides ATimesFn function pointer, as well as a void * pointer to a data structure used by this routine, to a linear solver object. SUNDIALS solvers will call this function to set the matrix-vector product function to either a solver-provided difference-quotient via vector operations or a user-supplied solver-specific routine. This routine should return zero for a successful call, and a negative value for a failure, ideally returning one of the generic error codes listed in Table 8.4.
	continued on next page

Name	Usage and Description
SUNLinSolSetPreconditioner	ier = SUNLinSolSetPreconditioner(LS, Pdata, Pset, Psol); (Optional; Iterative/Custom linear solvers only) Provides PSetupFn and PSolveFn function pointers that implement the preconditioner solves P_1^{-1} and P_2^{-1} from equations (8.1)-(8.2). This routine will be called by a SUNDIALS solver, which will provide translation between the generic Pset and Psol calls and the integrator-specific and integrator- or user-supplied routines. This routine should return zero for a successful call, and a negative value for a failure, ideally returning one of the generic error codes listed in Table 8.4.
SUNLinSolSetScalingVectors	ier = SUNLinSolSetScalingVectors (LS, $s1$, $s2$); (Optional; Iterative/Custom linear solvers only) Sets pointers to left/right scaling vectors for the linear system solve. Here, $s1$ is an NVECTOR of positive scale factors containing the diagonal of the matrix S_1 from equations (8.1)-(8.2). Similarly, $s2$ is an NVECTOR containing the diagonal of S_2 from equations (8.1)-(8.2). Neither of these vectors are tested for positivity, and a NULL argument for either indicates that the corresponding scaling matrix is the identity. This routine should return zero for a successful call, and a negative value for a failure, ideally returning one of the generic error codes listed in Table 8.4.
SUNLinSolNumIters	<pre>its = SUNLinSolNumIters(LS); (Optional; Iterative/Custom linear solvers only) Should return the int number of linear iterations performed in the last 'solve' call.</pre>
SUNLinSolResNorm	<pre>rnorm = SUNLinSolResNorm(LS); (Optional; Iterative/Custom linear solvers only) Should return the realtype final residual norm from the last 'solve' call.</pre>
SUNLinSolResid	rvec = SUNLinSolResid(LS); (Optional; Iterative/Custom linear solvers only) If an iterative method computes the preconditioned initial residual and returns with a successful solve without performing any iterations (i.e. either the initial guess or the preconditioner is sufficiently accurate), then this function may be called by the SUNDIALS solver. This routine should return the NVECTOR containing the preconditioned initial residual vector.
	continued on next page

Name	Usage and Description
SUNLinLastFlag	lflag = SUNLinLastFlag(LS); (Optional) Should return the last error flag encountered within the linear solver. This is not called by the SUNDIALS solvers directly; it allows the user to investigate linear solver issues after a failed solve.
SUNLinSolSpace	ier = SUNLinSolSpace(LS, &lrw, &liw); (Optional) Returns the storage requirements for the linear solver LS. lrw is a long int containing the number of realtype words and liw is a long int containing the number of integer words. The return value is an integer flag denoting success/failure of the operation. This function is advisory only, for use in determining a user's total space requirements.

8.1 Description of the client-supplied SUNLinearSolver routines

The SUNDIALS packages provide the ATimes, Pset and Psol routines utilized by the SUNLINSOL modules. These function types are defined in the header file sundials/sundials_iterative.h, and are described here in case a user wishes to interact directly with an iterative SUNLINSOL object.

ATimesFn

Definition typedef int (*ATimesFn)(void *A_data, N_Vector v, N_Vector z);

Purpose These functions compute the action of a matrix on a vector, performing the operation

z=Av. Memory for ${f z}$ should already be allocted prior to calling this function. The

vector v should be left unchanged.

Arguments A_data is a pointer to client data, the same as that supplied to SUNLinSolSetATimes.

v is the input vector to multiply.

z is the output vector computed.

Return value This routine should return 0 if successful and a non-zero value if unsuccessful.

Notes

PSetupFn

Definition typedef int (*PSetupFn)(void *P_data)

Purpose These functions set up any requisite problem data in preparation for calls to the corre-

sponding PSolveFn.

Arguments P_data is a pointer to client data, the same pointer as that supplied to the routine

SUNLinSolSetPreconditioner.

Return value This routine should return 0 if successful and a non-zero value if unsuccessful.

Notes

PSolveFn

Definition typedef int (*PSolveFn)(void *P_data, N_Vector r, N_Vector z, realtype tol, int lr)

Purpose

These functions solve the preconditioner equation Pz = r for the vector z. Memory for z should already be allocted prior to calling this function. The parameter P_data is a pointer to any information about P which the function needs in order to do its job (set up by the corresponding PSetupFn. The parameter lr is input, and indicates whether P is to be taken as the left preconditioner or the right preconditioner: lr = 1 for left and 1r = 2 for right. If preconditioning is on one side only, 1r can be ignored. If the preconditioner is iterative, then it should strive to solve the preconditioner equation so that

$$||Pz - r||_{\text{wrms}} < tol$$

where the weight vector for the WRMS norm may be accessed from the main package memory structure. The vector r should not be modified by the PSolveFn.

Arguments

P_data is a pointer to client data, the same pointer as that supplied to the routine SUNLinSolSetPreconditioner.

- is the right-hand side vector for the preconditioner system
- z is the solution vector for the preconditioner system

tol is the desired tolerance for an iterative preconditioner

1r is flag indicating whether the routine should perform left (1) or right (2) preconditioning.

Return value This routine should return 0 if successful and a non-zero value if unsuccessful. On a failure, a negative return value indicates an unrecoverable condition, while a positive value indicates a recoverable one, in which the calling routine may reattempt the solution after updating preconditioner data.

Notes

8.2 Compatibility of SUNLinear Solver modules

We note that not all SUNLINSOL types are compatible with all SUNMATRIX and NVECTOR types provided with SUNDIALS. In Table 8.3 we show the direct linear solvers available as SUNLINSOL modules, and the compatible matrix implementations. Recall that Table 4.1 shows the compatibility between all SUNLINSOL modules and vector implementations.

Tab	le 8.3:	SUNDIALS	direct	linear	solvers	and	matrix	imp.	lement	ations	that	can	be	used	for	each	n.

The functions within the SUNDIALS-provided SUNLinearSolver implementations return a common set of error codes, shown below in the Table 8.4.

Table 8.4: Description of the SUNLinearSolver error codes

		tion of the SUNLinearSolver error codes
Name	Value	Description
SUNLS_SUCCESS	0	successful call or converged solve
SUNLS_MEM_NULL	-1	the memory argument to the function is NULL
SUNLS_ILL_INPUT	-2	an illegal input has been provided to the function
SUNLS_MEM_FAIL	-3	failed memory access or allocation
SUNLS_ATIMES_FAIL_UNREC	-4	an unrecoverable failure occurred in the ATimes routine
SUNLS_PSET_FAIL_UNREC	-5	an unrecoverable failure occurred in the Pset routine
SUNLS_PSOLVE_FAIL_UNREC	-6	an unrecoverable failure occurred in the Psolve routine
SUNLS_PACKAGE_FAIL_UNREC	-7	an unrecoverable failure occurred in an external linear solver package
SUNLS_GS_FAIL	-8	a failure occurred during Gram-Schmidt orthogonalization (SUNLINSOL_SPGMR/SUNLINSOL_SPFGMR)
SUNLS_QRSOL_FAIL	-9	a singular R matrix was encountered in a QR factorization (SUNLINSOL_SPGMR/SUNLINSOL_SPFGMR)
SUNLS_RES_REDUCED	1	an iterative solver reduced the residual, but did not converge to the desired tolerance
SUNLS_CONV_FAIL	2	an iterative solver did not converge (and the residual was not reduced)
SUNLS_ATIMES_FAIL_REC	3	a recoverable failure occurred in the ATimes routine
SUNLS_PSET_FAIL_REC	4	a recoverable failure occurred in the Pset routine
SUNLS_PSOLVE_FAIL_REC	5	a recoverable failure occurred in the Psolve routine
SUNLS_PACKAGE_FAIL_REC	6	a recoverable failure occurred in an external linear solver package
SUNLS_QRFACT_FAIL	7	a singular matrix was encountered during a QR factorization (SUNLINSOL_SPGMR/SUNLINSOL_SPFGMR)
SUNLS_LUFACT_FAIL	8	a singular matrix was encountered during a LU factorization (SUNLINSOL_DENSE/SUNLINSOL_BAND)

8.3 The SUNLinearSolver_Dense implementation

The dense implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL_DENSE, is designed to be used with the corresponding SUNMATRIX_DENSE matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR_SERIAL, NVECTOR_OPENMP or NVECTOR_PTHREADS). The SUNLINSOL_DENSE module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_Dense {
  sunindextype N;
  sunindextype *pivots;
```

```
long int last_flag;
};
```

These entries of the *content* field contain the following information:

N - size of the linear system,

pivots - index array for partial pivoting in LU factorization,

last_flag - last error return flag from internal function evaluations.

This solver is constructed to perform the following operations:

- The "setup" call performs a LU factorization with partial (row) pivoting $(\mathcal{O}(N^3) \cos t)$, PA = LU, where P is a permutation matrix, L is a lower triangular matrix with 1's on the diagonal, and U is an upper triangular matrix. This factorization is stored in-place on the input SUNMATRIX_DENSE object A, with pivoting information encoding P stored in the pivots array.
- The "solve" call performs pivoting and forward and backward substitution using the stored pivots array and the LU factors held in the SUNMATRIX_DENSE object $(\mathcal{O}(N^2) \text{ cost})$.

The header file to include when using this module is sunlinsol/sunlinsol_dense.h. The SUNLINSOL_DENSE module is accessible from all SUNDIALS solvers without linking to the

libsundials_sunlinsoldense module library.

The SUNLINSOL_DENSE module defines dense implementations of all "direct" linear solver operations listed in Table 8.2:

- SUNLinSolGetType_Dense
- SUNLinSolInitialize_Dense this does nothing, since all consistency checks are performed at solver creation.
- SUNLinSolSetup_Dense this performs the LU factorization.
- SUNLinSolSolve_Dense this uses the LU factors and pivots array to perform the solve.
- SUNLinSolLastFlag_Dense
- SUNLinSolSpace_Dense this only returns information for the storage within the solver object, i.e. storage for N, last_flag, and pivots.
- SUNLinSolFree_Dense

The module SUNLINSOL_DENSE provides the following additional user-callable constructor routine:

• SUNDenseLinearSolver

This function creates and allocates memory for a dense SUNLinearSolver. Its arguments are an NVECTOR and SUNMATRIX, that it uses to determine the linear system size and to assess compatibility with the linear solver implementation.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX_DENSE matrix type and the NVECTOR_SERIAL, NVECTOR_OPENMP, and NVECTOR_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

If either A or y are incompatible then this routine will return NULL.

```
SUNLinearSolver SUNDenseLinearSolver(N_Vector y, SUNMatrix A);
```

For solvers that include a Fortran interface module, the SUNLINSOL_DENSE module also includes the Fortran-callable function FSUNDenseLinSolInit(code, ier) to initialize this SUNLINSOL_DENSE module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. This routine must be called *after* both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassDenseLinSolInit(ier) initializes this SUNLINSOL_DENSE module for solving mass matrix linear systems.

8.4 The SUNLinearSolver_Band implementation

The band implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL_BAND, is designed to be used with the corresponding SUNMATRIX_BAND matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR_SERIAL, NVECTOR_OPENMP or NVECTOR_PTHREADS). The SUNLINSOL_BAND module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_Band {
   sunindextype N;
   sunindextype *pivots;
   long int last_flag;
};
```

These entries of the *content* field contain the following information:

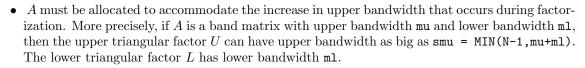

N - size of the linear system,

pivots - index array for partial pivoting in LU factorization,

last_flag - last error return flag from internal function evaluations.

This solver is constructed to perform the following operations:

- The "setup" call performs a LU factorization with partial (row) pivoting, PA = LU, where P is a permutation matrix, L is a lower triangular matrix with 1's on the diagonal, and U is an upper triangular matrix. This factorization is stored in-place on the input SUNMATRIX_BAND object A, with pivoting information encoding P stored in the pivots array.
- The "solve" call performs pivoting and forward and backward substitution using the stored pivots array and the LU factors held in the SUNMATRIX_BAND object.

The header file to include when using this module is sunlinsol_band.h. The SUNLIN-SOL_BAND module is accessible from all SUNDIALS solvers without linking to the

libsundials_sunlinsolband module library.

The SUNLINSOL_BAND module defines band implementations of all "direct" linear solver operations listed in Table 8.2:

- SUNLinSolGetType_Band
- SUNLinSolInitialize_Band this does nothing, since all consistency checks are performed at solver creation.
- SUNLinSolSetup_Band this performs the *LU* factorization.

- SUNLinSolSolve_Band this uses the LU factors and pivots array to perform the solve.
- SUNLinSolLastFlag_Band
- SUNLinSolSpace_Band this only returns information for the storage within the solver object, i.e. storage for N, last_flag, and pivots.
- SUNLinSolFree_Band

The module SUNLINSOL_BAND provides the following additional user-callable constructor routine:

• SUNBandLinearSolver

This function creates and allocates memory for a band SUNLinearSolver. Its arguments are an NVECTOR and SUNMATRIX, that it uses to determine the linear system size and to assess compatibility with the linear solver implementation.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX_BAND matrix type and the NVECTOR_SERIAL, NVECTOR_OPENMP, and NVECTOR_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

Additionally, this routine will verify that the input matrix A is allocated with appropriate upper bandwidth storage for the LU factorization.

If either A or y are incompatible then this routine will return NULL.

```
SUNLinearSolver SUNBandLinearSolver(N_Vector y, SUNMatrix A);
```

For solvers that include a Fortran interface module, the SUNLINSOL_BAND module also includes the Fortran-callable function FSUNBandLinSolInit(code, ier) to initialize this SUNLINSOL_BAND module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. This routine must be called *after* both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassBandLinSolInit(ier) initializes this SUNLINSOL_BAND module for solving mass matrix linear systems.

8.5 The SUNLinearSolver_LapackDense implementation

The LAPACK dense implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL_LAPACKDENSE, is designed to be used with the corresponding SUNMATRIX_DENSE matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR_SERIAL, NVECTOR_OPENMP, or NVECTOR_PTHREADS). The SUNLINSOL_LAPACKDENSE module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_Dense {
   sunindextype N;
   sunindextype *pivots;
   long int last_flag;
};
```

These entries of the *content* field contain the following information:

N - size of the linear system,

pivots - index array for partial pivoting in LU factorization,

last_flag - last error return flag from internal function evaluations.

The SUNLINSOL_LAPACKDENSE module is a SUNLINSOL wrapper for the LAPACK dense matrix factorization and solve routines, *GETRF and *GETRS, where * is either D or S, depending on whether SUNDIALS was configured to have realtype set to double or single, respectively (see Section 4.2). In order to use the SUNLINSOL_LAPACKDENSE module it is assumed that LAPACK has been installed on the system prior to installation of SUNDIALS, and that SUNDIALS has been configured appropriately to link with LAPACK (see Appendix A for details). We note that since there do not exist 128-bit floating-point factorization and solve routines in LAPACK, this interface cannot be compiled when using extended precision for realtype. Similarly, since there do not exist 64-bit integer LAPACK routines, the SUNLINSOL_LAPACKDENSE module also cannot be compiled when using int64_t for the sunindextype.

This solver is constructed to perform the following operations:

- The "setup" call performs a LU factorization with partial (row) pivoting $(\mathcal{O}(N^3) \cos t)$, PA = LU, where P is a permutation matrix, L is a lower triangular matrix with 1's on the diagonal, and U is an upper triangular matrix. This factorization is stored in-place on the input SUNMATRIX_DENSE object A, with pivoting information encoding P stored in the pivots array.
- The "solve" call performs pivoting and forward and backward substitution using the stored pivots array and the LU factors held in the SUNMATRIX_DENSE object $(\mathcal{O}(N^2) \text{ cost})$.

The header file to include when using this module is sunlinsol/sunlinsol_lapackdense.h. The installed module library to link to is libsundials_sunlinsollapackdense.lib where .lib is typically .so for shared libraries and .a for static libraries.

The SUNLINSOL_LAPACKDENSE module defines dense implementations of all "direct" linear solver operations listed in Table 8.2:

- SUNLinSolGetType_LapackDense
- SUNLinSolInitialize_LapackDense this does nothing, since all consistency checks are performed at solver creation.
- ullet SUNLinSolSetup_LapackDense this calls either DGETRF or SGETRF to perform the LU factorization.
- SUNLinSolSolve_LapackDense this calls either DGETRS or SGETRS to use the *LU* factors and pivots array to perform the solve.
- SUNLinSolLastFlag_LapackDense
- SUNLinSolSpace_LapackDense this only returns information for the storage within the solver object, i.e. storage for N, last_flag, and pivots.
- SUNLinSolFree_LapackDense

The module SUNLINSOL_LAPACKDENSE provides the following additional user-callable constructor routine:

• SUNLapackDense

This function creates and allocates memory for a LAPACK dense SUNLinearSolver. Its arguments are an NVECTOR and SUNMATRIX, that it uses to determine the linear system size and to assess compatibility with the linear solver implementation.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX_DENSE matrix type and the NVECTOR_SERIAL, NVECTOR_OPENMP, and NVECTOR_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

If either A or y are incompatible then this routine will return NULL.

SUNLinearSolver SUNLapackDense(N_Vector y, SUNMatrix A);

For solvers that include a Fortran interface module, the SUNLINSOL_LAPACKDENSE module also includes the Fortran-callable function FSUNLapackDenseInit(code, ier) to initialize this SUNLINSOL_LAPACKDENSE module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. This routine must be called after both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassLapackDenseInit(ier) initializes this SUNLINSOL_LAPACKDENSE module for solving mass matrix linear systems.

8.6 The SUNLinearSolver_LapackBand implementation

The LAPACK band implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL_LAPACKBAND, is designed to be used with the corresponding SUNMATRIX_BAND matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR_SERIAL, NVECTOR_OPENMP, or NVECTOR_PTHREADS). The SUNLINSOL_LAPACKBAND module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_Band {
   sunindextype N;
   sunindextype *pivots;
   long int last_flag;
};
```

These entries of the *content* field contain the following information:

N - size of the linear system,

pivots - index array for partial pivoting in LU factorization,

last_flag - last error return flag from internal function evaluations.

The SUNLINSOL_LAPACKBAND module is a SUNLINSOL wrapper for the LAPACK band matrix factorization and solve routines, *GBTRF and *GBTRS, where * is either D or S, depending on whether SUNDIALS was configured to have realtype set to double or single, respectively (see Section 4.2). In order to use the SUNLINSOL_LAPACKBAND module it is assumed that LAPACK has been installed on the system prior to installation of SUNDIALS, and that SUNDIALS has been configured appropriately to link with LAPACK (see Appendix A for details). We note that since there do not exist 128-bit floating-point factorization and solve routines in LAPACK, this interface cannot be compiled when using extended precision for realtype. Similarly, since there do not exist 64-bit integer LAPACK routines, the SUNLINSOL_LAPACKBAND module also cannot be compiled when using int64_t for the sunindextype.

This solver is constructed to perform the following operations:

- The "setup" call performs a LU factorization with partial (row) pivoting, PA = LU, where P is a permutation matrix, L is a lower triangular matrix with 1's on the diagonal, and U is an upper triangular matrix. This factorization is stored in-place on the input SUNMATRIX_BAND object A, with pivoting information encoding P stored in the pivots array.
- The "solve" call performs pivoting and forward and backward substitution using the stored pivots array and the *LU* factors held in the SUNMATRIX_BAND object.
- A must be allocated to accommodate the increase in upper bandwidth that occurs during factorization. More precisely, if A is a band matrix with upper bandwidth mu and lower bandwidth ml, then the upper triangular factor U can have upper bandwidth as big as smu = MIN(N-1,mu+ml). The lower triangular factor L has lower bandwidth ml.

The header file to include when using this module is sunlinsol_lapackband.h. The installed module library to link to is libsundials_sunlinsollapackband. lib where . lib is typically .so for shared libraries and .a for static libraries.

The SUNLINSOL_LAPACKBAND module defines band implementations of all "direct" linear solver operations listed in Table 8.2:

- SUNLinSolGetType_LapackBand
- SUNLinSolInitialize_LapackBand this does nothing, since all consistency checks are performed at solver creation.
- ullet SUNLinSolSetup_LapackBand this calls either DGBTRF or SGBTRF to perform the LU factorization.
- SUNLinSolSolve_LapackBand this calls either DGBTRS or SGBTRS to use the *LU* factors and pivots array to perform the solve.
- SUNLinSolLastFlag_LapackBand
- SUNLinSolSpace_LapackBand this only returns information for the storage within the solver object, i.e. storage for N, last_flag, and pivots.
- SUNLinSolFree_LapackBand

The module SUNLINSOL_LAPACKBAND provides the following additional user-callable routine:

• SUNLapackBand

This function creates and allocates memory for a LAPACK band SUNLinearSolver. Its arguments are an NVECTOR and SUNMATRIX, that it uses to determine the linear system size and to assess compatibility with the linear solver implementation.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX_BAND matrix type and the NVECTOR_SERIAL, NVECTOR_OPENMP, and NVECTOR_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

Additionally, this routine will verify that the input matrix A is allocated with appropriate upper bandwidth storage for the LU factorization.

If either A or y are incompatible then this routine will return NULL.

SUNLinearSolver SUNLapackBand(N_Vector y, SUNMatrix A);

For solvers that include a Fortran interface module, the SUNLINSOL_LAPACKBAND module also includes the Fortran-callable function FSUNLapackBandInit(code, ier) to initialize this SUNLINSOL_LAPACKBAND module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. This routine must be called after both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassLapackBandInit(ier) initializes this SUNLINSOL_LAPACKBAND module for solving mass matrix linear systems.

8.7 The SUNLinearSolver_KLU implementation

The KLU implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL_KLU, is designed to be used with the corresponding SUNMATRIX_SPARSE matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR_SERIAL, NVECTOR_OPENMP, or NVECTOR_PTHREADS). The SUNLINSOL_KLU module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_KLU {
                     last_flag;
  long int
  int
                     first_factorize;
  sun_klu_symbolic *symbolic;
  sun_klu_numeric *numeric;
  sun_klu_common
                     common;
  sunindextype
                     (*klu_solver)(sun_klu_symbolic*, sun_klu_numeric*,
                                    sunindextype, sunindextype,
                                    double*, sun_klu_common*);
};
These entries of the content field contain the following information:
last_flag - last error return flag from internal function evaluations,
first_factorize - flag indicating whether the factorization has ever been performed,
```

symbolic - KLU storage structure for symbolic factorization components,

numeric - KLU storage structure for numeric factorization components,

common - storage structure for common KLU solver components,

klu_solver - pointer to the appropriate KLU solver function (depending on whether it is using a CSR or CSC sparse matrix).

The SUNLINSOL_KLU module is a SUNLINSOL wrapper for the KLU sparse matrix factorization and solver library written by Tim Davis [1, 14]. In order to use the SUNLINSOL_KLU interface to KLU, it is assumed that KLU has been installed on the system prior to installation of SUNDIALS, and that SUNDIALS has been configured appropriately to link with KLU (see Appendix A for details). Additionally, this wrapper only supports double-precision calculations, and therefore cannot be compiled if SUNDIALS is configured to have realtype set to either extended or single (see Section 4.2). Since the KLU library supports both 32-bit and 64-bit integers, this interface will be compiled for either of the available sunindextype options.

The KLU library has a symbolic factorization routine that computes the permutation of the linear system matrix to block triangular form and the permutations that will pre-order the diagonal blocks (the only ones that need to be factored) to reduce fill-in (using AMD, COLAMD, CHOLAMD, natural, or an ordering given by the user). Of these ordering choices, the default value in the SUNLINSOL_KLU module is the COLAMD ordering.

KLU breaks the factorization into two separate parts. The first is a symbolic factorization and the second is a numeric factorization that returns the factored matrix along with final pivot information. KLU also has a refactor routine that can be called instead of the numeric factorization. This routine will reuse the pivot information. This routine also returns diagnostic information that a user can examine to determine if numerical stability is being lost and a full numerical factorization should be done instead of the refactor.

Since the linear systems that arise within the context of SUNDIALS calculations will typically have identical sparsity patterns, the SUNLINSOL_KLU module is constructed to perform the following operations:

- The first time that the "setup" routine is called, it performs the symbolic factorization, followed by an initial numerical factorization.
- On subsequent calls to the "setup" routine, it calls the appropriate KLU "refactor" routine, followed by estimates of the numerical conditioning using the relevant "rcond", and if necessary "condest", routine(s). If these estimates of the condition number are larger than $\varepsilon^{-2/3}$ (where ε is the double-precision unit roundoff), then a new factorization is performed.
- The module includes the routine SUNKLUReInit, that can be called by the user to force a full or partial refactorization at the next "setup" call.

• The "solve" call performs pivoting and forward and backward substitution using the stored KLU data structures. We note that in this solve KLU operates on the native data arrays for the right-hand side and solution vectors, without requiring costly data copies.

The header file to include when using this module is sunlinsol/sunlinsol_klu.h. The installed module library to link to is libsundials_sunlinsolklu.lib where .lib is typically .so for shared libraries and .a for static libraries.

The SUNLINSOL_KLU module defines implementations of all "direct" linear solver operations listed in Table 8.2:

- SUNLinSolGetType_KLU
- SUNLinSolInitialize_KLU this sets the first_factorize flag to 1, forcing both symbolic and numerical factorizations on the subsequent "setup" call.
- SUNLinSolSetup_KLU this performs either a *LU* factorization or refactorization of the input matrix.
- SUNLinSolSolve_KLU this calls the appropriate KLU solve routine to utilize the *LU* factors to solve the linear system.
- SUNLinSolLastFlag_KLU
- SUNLinSolSpace_KLU this only returns information for the storage within the solver *interface*, i.e. storage for the integers last_flag and first_factorize. For additional space requirements, see the KLU documentation.
- SUNLinSolFree_KLU

The module SUNLINSOL_KLU provides the following additional user-callable routines:

• SUNKLU

This constructor function creates and allocates memory for a SUNLINSOL_KLU object. Its arguments are an NVECTOR and SUNMATRIX, that it uses to determine the linear system size and to assess compatibility with the linear solver implementation.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX_SPARSE matrix type (using either CSR or CSC storage formats) and the NVECTOR_SERIAL, NVECTOR_OPENMP, and NVECTOR_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

If either A or y are incompatible then this routine will return NULL.

SUNLinearSolver SUNKLU(N_Vector y, SUNMatrix A);

• SUNKLUReInit

This function reinitializes memory and flags for a new factorization (symbolic and numeric) to be conducted at the next solver setup call. This routine is useful in the cases where the number of nonzeroes has changed or if the structure of the linear system has changed which would require a new symbolic (and numeric factorization).

The reinit_type argument governs the level of reinitialization. The allowed values are:

- SUNKLU_REINIT_FULL The Jacobian matrix will be destroyed and a new one will be allocated based on the nnz value passed to this call. New symbolic and numeric factorizations will be completed at the next solver setup.
- SUNKLU_REINIT_PARTIAL Only symbolic and numeric factorizations will be completed. It is assumed that the Jacobian size has not exceeded the size of nnz given in the sparse matrix provided to the original constructor routine (or the previous SUNKLUReInit call).

This routine assumes no other changes to solver use are necessary.

The return values from this function are SUNLS_MEM_NULL (either S or A are NULL), SUNLS_ILL_INPUT (A does not have type SUNMATRIX_SPARSE or reinit_type is invalid), SUNLS_MEM_FAIL (reallocation of the sparse matrix failed) or SUNLS_SUCCESS.

• SUNKLUSetOrdering

This function sets the ordering used by KLU for reducing fill in the linear solve. Options for ordering_choice are:

- 0 AMD,
- 1 COLAMD, and
- 2 the natural ordering.

The default is 1 for COLAMD.

The return values from this function are SUNLS_MEM_NULL (S is NULL), SUNLS_ILL_INPUT (invalid ordering_choice), or SUNLS_SUCCESS.

```
int SUNKLUSetOrdering(SUNLinearSolver S, int ordering_choice);
```

For solvers that include a Fortran interface module, the SUNLINSOL_KLU module also includes the Fortran-callable function FSUNKLUInit(code, ier) to initialize this SUNLINSOL_KLU module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. This routine must be called *after* both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassKLUInit(ier) initializes this SUNLINSOL_KLU module for solving mass matrix linear systems.

The SUNKLUReInit and SUNKLUSetOrdering routines also support Fortran interfaces for the system and mass matrix solvers:

- FSUNKLUReInit(code, NNZ, reinit_type, ier) NNZ should be commensurate with a C long int and reinit_type should be commensurate with a C int (1 = 'FULL', 2 = 'PARTIAL')
- FSUNMassKLUReInit(NNZ, reinit_type, ier)
- FSUNKLUSetOrdering(code, ordering, ier) ordering should be commensurate with a C int
- FSUNMassKLUSetOrdering(ordering, ier)

8.8 The SUNLinearSolver_SuperLUMT implementation

The SUPERLUMT implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL_SUPERLUMT, is designed to be used with the corresponding SUNMATRIX_SPARSE matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR_SERIAL, NVECTOR_OPENMP, or NVECTOR_PTHREADS). While these are compatible, it is not recommended to use a threaded vector module with SUNLINSOL_SUPERLUMT unless it is the NVECTOR_OPENMP module and the SUPERLUMT library has also been compiled with OpenMP. The SUNLINSOL_SUPERLUMT module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_SuperLUMT {
  long int
                 last_flag;
  int
                 first_factorize;
  SuperMatrix
               *A, *AC, *L, *U, *B;
  Gstat_t
                 *Gstat:
  sunindextype *perm_r, *perm_c;
  sunindextype N;
  int
                num_threads;
                diag_pivot_thresh;
  realtype
  int
                 ordering;
  superlumt_options_t *options;
};
These entries of the content field contain the following information:
last_flag - last error return flag from internal function evaluations,
first_factorize - flag indicating whether the factorization has ever been performed,
A, AC, L, U, B - SuperMatrix pointers used in solve,
Gstat - GStat_t object used in solve,
perm_r, perm_c - permutation arrays used in solve,
N - size of the linear system,
num_threads - number of OpenMP/Pthreads threads to use,
diag_pivot_thresh - threshold on diagonal pivoting,
ordering - flag for which reordering algorithm to use,
options - pointer to SUPERLUMT options structure.
```

The SUNLINSOL_SUPERLUMT module is a SUNLINSOL wrapper for the SUPERLUMT sparse matrix factorization and solver library written by X. Sherry Li [2, 31, 16]. The package performs matrix factorization using threads to enhance efficiency in shared memory parallel environments. It should be noted that threads are only used in the factorization step. In order to use the SUNLINSOL_SUPERLUMT interface to SUPERLUMT, it is assumed that SUPERLUMT has been installed on the system prior to installation of SUNDIALS, and that SUNDIALS has been configured appropriately to link with SUPERLUMT (see Appendix A for details). Additionally, this wrapper only supports single- and double-precision calculations, and therefore cannot be compiled if SUNDIALS is configured to have realtype set to extended (see Section 4.2). Moreover, since the SUPERLUMT library may be installed to support either 32-bit or 64-bit integers, it is assumed that the SUPERLUMT library is installed using the same integer precision as the SUNDIALS sunindextype option.

The SUPERLUMT library has a symbolic factorization routine that computes the permutation of the linear system matrix to reduce fill-in on subsequent LU factorizations (using COLAMD, minimal degree ordering on $A^T * A$, minimal degree ordering on $A^T + A$, or natural ordering). Of these ordering choices, the default value in the SUNLINSOL_SUPERLUMT module is the COLAMD ordering.

Since the linear systems that arise within the context of SUNDIALS calculations will typically have identical sparsity patterns, the SUNLINSOL_SUPERLUMT module is constructed to perform the following operations:

- The first time that the "setup" routine is called, it performs the symbolic factorization, followed by an initial numerical factorization.
- On subsequent calls to the "setup" routine, it skips the symbolic factorization, and only refactors the input matrix.

• The "solve" call performs pivoting and forward and backward substitution using the stored SUPERLUMT data structures. We note that in this solve SUPERLUMT operates on the native data arrays for the right-hand side and solution vectors, without requiring costly data copies.

The header file to include when using this module is sunlinsol/sunlinsol_superlumt.h. The installed module library to link to is libsundials_sunlinsolsuperlumt.lib where .lib is typically .so for shared libraries and .a for static libraries.

The SUNLINSOL_SUPERLUMT module defines implementations of all "direct" linear solver operations listed in Table 8.2:

- SUNLinSolGetType_SuperLUMT
- SUNLinSolInitialize_SuperLUMT this sets the first_factorize flag to 1 and resets the internal SUPERLUMT statistics variables.
- SUNLinSolSetup_SuperLUMT this performs either a *LU* factorization or refactorization of the input matrix.
- SUNLinSolSolve_SuperLUMT this calls the appropriate SUPERLUMT solve routine to utilize the *LU* factors to solve the linear system.
- SUNLinSolLastFlag_SuperLUMT
- SUNLinSolSpace_SuperLUMT this only returns information for the storage within the solver *interface*, i.e. storage for the integers last_flag and first_factorize. For additional space requirements, see the SUPERLUMT documentation.
- SUNLinSolFree_SuperLUMT

The module SUNLINSOL_SUPERLUMT provides the following additional user-callable routines:

• SUNSuperLUMT

This constructor function creates and allocates memory for a SUNLINSOL_SUPERLUMT object. Its arguments are an NVECTOR, a SUNMATRIX, and a desired number of threads (OpenMP or Pthreads, depending on how SUPERLUMT was installed) to use during the factorization steps. This routine analyzes the input matrix and vector to determine the linear system size and to assess compatibility with the SUPERLUMT library.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX_SPARSE matrix type (using either CSR or CSC storage formats) and the NVECTOR_SERIAL, NVECTOR_OPENMP, and NVECTOR_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

If either A or y are incompatible then this routine will return NULL. The num_threads argument is not checked and is passed directly to SUPERLUMT routines.

SUNLinearSolver SUNSuperLUMT(N_Vector y, SUNMatrix A, int num_threads);

• SUNSuperLUMTSetOrdering

This function sets the ordering used by SUPERLUMT for reducing fill in the linear solve. Options for ordering_choice are:

- 0 natural ordering
- 1 minimal degree ordering on A^TA
- 2 minimal degree ordering on $A^T + A$
- 3 COLAMD ordering for unsymmetric matrices

The default is 3 for COLAMD.

The return values from this function are SUNLS_MEM_NULL (S is NULL), SUNLS_ILL_INPUT (invalid ordering_choice), or SUNLS_SUCCESS.

```
int SUNSuperLUMTSetOrdering(SUNLinearSolver S, int ordering_choice);
```

For solvers that include a Fortran interface module, the SUNLINSOL_SUPERLUMT module also includes the Fortran-callable function FSUNSuperLUMTInit(code, num_threads, ier) to initialize this SUNLINSOL_SUPERLUMT module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); num_threads is the desired number of Open-MP/Pthreads threads to use in the factorization; ier is an error return flag equal to 0 for success and -1 for failure. All of these arguments should be declared so as to match C type int. This routine must be called after both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassSuperLUMTInit(num_threads, ier) initializes this SUNLINSOL_SUPERLUMT module for solving mass matrix linear systems.

The SUNSuperLUMTSetOrdering routine also supports Fortran interfaces for the system and mass matrix solvers:

- FSUNSuperLUMTSetOrdering(code, ordering, ier) ordering should be commensurate with a C int
- FSUNMassSuperLUMTSetOrdering(ordering, ier)

8.9 The SUNLinearSolver_SPGMR implementation

The SPGMR (Scaled, Preconditioned, Generalized Minimum Residual [36]) implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL_SPGMR, is an iterative linear solver that is designed to be compatible with any NVECTOR implementation (serial, threaded, parallel, and user-supplied) that supports a minimal subset of operations (N_VClone, N_VDotProd, N_VScale, N_VLinearSum, N_VProd, N_VConst, N_VDiv, and N_VDestroy).

The $\mathtt{SUNLINSOL_SPGMR}$ module defines the content field of a $\mathtt{SUNLinearSolver}$ to be the following structure:

```
struct _SUNLinearSolverContent_SPGMR {
  int maxl;
  int pretype;
  int gstype;
  int max_restarts;
  int numiters;
  realtype resnorm;
  long int last_flag;
  ATimesFn ATimes;
  void* ATData;
  PSetupFn Psetup;
  PSolveFn Psolve;
  void* PData;
  N_Vector s1;
  N_Vector s2;
  N_Vector *V;
  realtype **Hes;
  realtype *givens;
  N_Vector xcor;
  realtype *yg;
  N_Vector vtemp;
};
```

These entries of the *content* field contain the following information:

maxl - number of GMRES basis vectors to use (default is 5),

pretype - flag for type of preconditioning to employ (default is none),

gstype - flag for type of Gram-Schmidt orthogonalization (default is modified Gram-Schmidt),

max_restarts - number of GMRES restarts to allow (default is 0),

numiters - number of iterations from the most-recent solve,

resnorm - final linear residual norm from the most-recent solve,

last_flag - last error return flag from an internal function,

ATimes - function pointer to perform Av product,

ATData - pointer to structure for ATimes,

Psetup - function pointer to preconditioner setup routine,

Psolve - function pointer to preconditioner solve routine,

PData - pointer to structure for Psetup and Psolve,

s1, s2 - vector pointers for supplied scaling matrices (default is NULL),

V - the array of Krylov basis vectors $v_1, \ldots, v_{\mathtt{maxl}+1}$, stored in $V[0], \ldots, V[\mathtt{maxl}]$. Each v_i is a vector of type NVECTOR.,

Hes - the $(\max 1 + 1) \times \max 1$ Hessenberg matrix. It is stored row-wise so that the (i,j)th element is given by Hes[i][j].,

givens - a length 2*maxl array which represents the Givens rotation matrices that arise in the GMRES

algorithm. These matrices are
$$F_0, F_1, \ldots, F_j$$
, where $F_i = \begin{bmatrix} 1 & & & & \\ & \ddots & & \\ & & 1 & & \\ & & c_i & -s_i & \\ & & s_i & c_i & \\ & & & 1 & \\ & & & \ddots & \\ & & & & 1 \end{bmatrix}$ are represented in the givens vector as givens [0] = c_0 , givens [1] = s_0 , givens [2] = c_1 ,

xcor - a vector which holds the scaled, preconditioned correction to the initial guess,

givens[3] = s_1, \dots givens[2j] = c_j , givens[2j+1] = s_j .

yg - a length (maxl+1) array of realtype values used to hold "short" vectors (e.g. y and g),

vtemp - temporary vector storage.

This solver is constructed to perform the following operations:

- During construction, the xcor and vtemp arrays are cloned from a template NVECTOR that is input, and default solver parameters are set.
- User-facing "set" routines may be called to modify default solver parameters.
- Additional "set" routines are called by the SUNDIALS solver that interfaces with SUNLINSOL_SPGMR to supply the ATimes, PSetup, and Psolve function pointers and s1 and s2 scaling vectors.

- In the "initialize" call, the remaining solver data is allocated (V, Hes, givens, and yg)
- In the "setup" call, any non-NULL PSetup function is called. Typically, this is provided by the SUNDIALS solver itself, that translates between the generic PSetup function and the solver-specific routine (solver-supplied or user-supplied).
- In the "solve" call, the GMRES iteration is performed. This will include scaling, preconditioning, and restarts if those options have been supplied.

The header file to include when using this module is sunlinsol/sunlinsol_spgmr.h. The SUNLIN-SOL_SPGMR module is accessible from all SUNDIALS solvers without linking to the

libsundials_sunlinsolspgmr module library.

The SUNLINSOL_SPGMR module defines implementations of all "iterative" linear solver operations listed in Table 8.2:

- SUNLinSolGetType_SPGMR
- SUNLinSolInitialize_SPGMR
- SUNLinSolSetATimes_SPGMR
- SUNLinSolSetPreconditioner_SPGMR
- SUNLinSolSetScalingVectors_SPGMR
- SUNLinSolSetup_SPGMR
- SUNLinSolSolve_SPGMR
- SUNLinSolNumIters_SPGMR
- SUNLinSolResNorm_SPGMR
- SUNLinSolResid_SPGMR
- SUNLinSolLastFlag_SPGMR
- SUNLinSolSpace_SPGMR
- SUNLinSolFree_SPGMR

The module SUNLINSOL_SPGMR provides the following additional user-callable routines:

• SUNSPGMR

This constructor function creates and allocates memory for a SPGMR SUNLinearSolver. Its arguments are an NVECTOR, the desired type of preconditioning, and the number of Krylov basis vectors to use.

This routine will perform consistency checks to ensure that it is called with a consistent NVECTOR implementation (i.e. that it supplies the requisite vector operations). If y is incompatible, then this routine will return NULL.

A max1 argument that is ≤ 0 will result in the default value (5).

Allowable inputs for pretype are PREC_NONE (0), PREC_LEFT (1), PREC_RIGHT (2) and PREC_BOTH (3); any other integer input will result in the default (no preconditioning). We note that some SUNDIALS solvers are designed to only work with left preconditioning (IDA and IDAS) and others with only right preconditioning (KINSOL). While it is possible to configure a SUNLINSOL_SPGMR object to use any of the preconditioning options with these solvers, this use mode is not supported and may result in inferior performance.

SUNLinearSolver SUNSPGMR(N_Vector y, int pretype, int maxl);

• SUNSPGMRSetPrecType

This function updates the type of preconditioning to use. Supported values are PREC_NONE (0), PREC_LEFT (1), PREC_RIGHT (2) and PREC_BOTH (3).

This routine will return with one of the error codes SUNLS_ILL_INPUT (illegal pretype), SUNLS_MEM_NULL (S is NULL) or SUNLS_SUCCESS.

int SUNSPGMRSetPrecType(SUNLinearSolver S, int pretype);

• SUNSPGMRSetGSType

This function sets the type of Gram-Schmidt orthogonalization to use. Supported values are MODIFIED_GS (1) and CLASSICAL_GS (2). Any other integer input will result in a failure, returning error code SUNLS_ILL_INPUT.

This routine will return with one of the error codes SUNLS_ILL_INPUT (illegal gstype), SUNLS_MEM_NULL (S is NULL) or SUNLS_SUCCESS.

int SUNSPGMRSetGSType(SUNLinearSolver S, int gstype);

• SUNSPGMRSetMaxRestarts

This function sets the number of GMRES restarts to allow. A negative input will result in the default of 0.

This routine will return with one of the error codes SUNLS_MEM_NULL (S is NULL) or SUNLS_SUCCESS. int SUNSPGMRSetMaxRestarts(SUNLinearSolver S, int maxrs);

For solvers that include a Fortran interface module, the SUNLINSOL_SPGMR module also includes the Fortran-callable function FSUNSPGMRInit(code, pretype, maxl, ier) to initialize this SUNLINSOL_SPGMR module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); pretype and maxl are the same as for the C function SUNSPGMR; ier is an error return flag equal to 0 for success and -1 for failure. All of these input arguments should be declared so as to match C type int. This routine must be called after the NVECTOR object has been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassSPGMRInit(pretype, maxl, ier) initializes this SUNLINSOL_SPGMR module for solving mass matrix linear systems.

The SUNSPGMRSetPrecType, SUNSPGMRSetGSType and SUNSPGMRSetMaxRestarts routines also support Fortran interfaces for the system and mass matrix solvers (all arguments should be commensurate with a C int):

- FSUNSPGMRSetGSType(code, gstype, ier)
- FSUNMassSPGMRSetGSType(gstype, ier)
- FSUNSPGMRSetPrecType(code, pretype, ier)
- FSUNMassSPGMRSetPrecType(pretype, ier)
- FSUNSPGMRSetMaxRS(code, maxrs, ier)
- FSUNMassSPGMRSetMaxRS(maxrs, ier)

8.10 The SUNLinearSolver_SPFGMR implementation

The SPFGMR (Scaled, Preconditioned, Flexible, Generalized Minimum Residual [35]) implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL_SPFGMR, is an iterative linear solver that is designed to be compatible with any NVECTOR implementation (serial, threaded, parallel, and user-supplied) that supports a minimal subset of operations (N_VClone, N_VDotProd, N_VScale, N_VLinearSum, N_VProd, N_VConst, N_VDiv, and N_VDestroy). Unlike the other Krylov iterative linear

solvers supplied with SUNDIALS, FGMRES is specifically designed to work with a changing preconditioner (e.g. from an iterative method).

The SUNLINSOL_SPFGMR module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_SPFGMR {
  int maxl;
  int pretype;
  int gstype;
  int max_restarts;
  int numiters;
  realtype resnorm;
  long int last_flag;
  ATimesFn ATimes;
  void* ATData;
  PSetupFn Psetup;
  PSolveFn Psolve;
  void* PData;
  N_Vector s1;
  N_Vector s2;
  N_Vector *V;
  N_Vector *Z;
  realtype **Hes;
  realtype *givens;
  N_Vector xcor;
  realtype *yg;
  N_Vector vtemp;
These entries of the content field contain the following information:
maxl - number of FGMRES basis vectors to use (default is 5),
pretype - flag for use of preconditioning (default is none),
gstype - flag for type of Gram-Schmidt orthogonalization (default is modified Gram-Schmidt),
max_restarts - number of FGMRES restarts to allow (default is 0),
numiters - number of iterations from the most-recent solve,
resnorm - final linear residual norm from the most-recent solve,
last_flag - last error return flag from an internal function,
ATimes - function pointer to perform Av product,
ATData - pointer to structure for ATimes,
Psetup - function pointer to preconditioner setup routine,
Psolve - function pointer to preconditioner solve routine,
PData - pointer to structure for Psetup and Psolve,
s1, s2 - vector pointers for supplied scaling matrices (default is NULL),
\mathbf V - the array of Krylov basis vectors v_1, \ldots, v_{\mathtt{maxl+1}}, stored in \mathtt V[\mathtt 0], \ldots, \mathtt V[\mathtt{maxl}]. Each v_i is a vector
     of type NVECTOR.,
```

Z - the array of preconditioned Krylov basis vectors $z_1, \ldots, z_{\texttt{maxl}+1}$, stored in Z[0], ..., Z[maxl]. Each z_i is a vector of type NVECTOR.,

Hes - the $(\max 1 + 1) \times \max 1$ Hessenberg matrix. It is stored row-wise so that the (i,j)th element is given by Hes[i][j].

givens - a length 2*maxl array which represents the Givens rotation matrices that arise in the FGM-

RES algorithm. These matrices are F_0, F_1, \ldots, F_j , where $F_i = \begin{bmatrix} 1 & & & & & \\ & \ddots & & & & \\ & & 1 & & & \\ & & c_i & -s_i & & \\ & & s_i & c_i & & \\ & & & 1 & & \\ & & & \ddots & & \\ & & & & 1 \end{bmatrix}$

are represented in the givens vector as givens $[0] = c_0$, givens $[1] = s_0$, givens $[2] = c_1$, givens $[3] = s_1$, ... givens $[2j] = c_j$, givens $[2j+1] = s_j$.

xcor - a vector which holds the scaled, preconditioned correction to the initial guess,

yg - a length (maxl+1) array of realtype values used to hold "short" vectors (e.g. y and g),

vtemp - temporary vector storage.

This solver is constructed to perform the following operations:

- During construction, the xcor and vtemp arrays are cloned from a template NVECTOR that is input, and default solver parameters are set.
- User-facing "set" routines may be called to modify default solver parameters.
- Additional "set" routines are called by the SUNDIALS solver that interfaces with SUNLINSOL_SPFGMR to supply the ATimes, PSetup, and Psolve function pointers and s1 and s2 scaling vectors.
- In the "initialize" call, the remaining solver data is allocated (V, Hes, givens, and vg)
- In the "setup" call, any non-NULL PSetup function is called. Typically, this is provided by the SUNDIALS solver itself, that translates between the generic PSetup function and the solver-specific routine (solver-supplied or user-supplied).
- In the "solve" call, the FGMRES iteration is performed. This will include scaling, preconditioning, and restarts if those options have been supplied.

The header file to include when using this module is sunlinsol/sunlinsol_spfgmr.h. The SUNLIN-SOL_SPFGMR module is accessible from all SUNDIALS solvers without linking to the

libsundials_sunlinsolspfgmr module library.

The SUNLINSOL_SPFGMR module defines implementations of all "iterative" linear solver operations listed in Table 8.2:

- SUNLinSolGetType_SPFGMR
- SUNLinSolInitialize_SPFGMR
- SUNLinSolSetATimes_SPFGMR
- SUNLinSolSetPreconditioner_SPFGMR
- $\bullet \ \mathtt{SUNLinSolSetScalingVectors_SPFGMR}$
- SUNLinSolSetup_SPFGMR

- SUNLinSolSolve_SPFGMR
- SUNLinSolNumIters_SPFGMR
- SUNLinSolResNorm_SPFGMR
- SUNLinSolResid_SPFGMR
- SUNLinSolLastFlag_SPFGMR
- SUNLinSolSpace_SPFGMR
- SUNLinSolFree_SPFGMR

The module SUNLINSOL_SPFGMR provides the following additional user-callable routines:

• SUNSPFGMR

This constructor function creates and allocates memory for a SPFGMR SUNLinearSolver. Its arguments are an NVECTOR, a flag indicating to use preconditioning, and the number of Krylov basis vectors to use.

This routine will perform consistency checks to ensure that it is called with a consistent NVECTOR implementation (i.e. that it supplies the requisite vector operations). If y is incompatible, then this routine will return NULL.

A max1 argument that is ≤ 0 will result in the default value (5).

Since the FGMRES algorithm is designed to only support right preconditioning, then any of the pretype inputs PREC_LEFT (1), PREC_RIGHT (2), or PREC_BOTH (3) will result in use of PREC_RIGHT; any other integer input will result in the default (no preconditioning). We note that some SUNDIALS solvers are designed to only work with left preconditioning (IDA and IDAS). While it is possible to use a right-preconditioned SUNLINSOL_SPFGMR object for these packages, this use mode is not supported and may result in inferior performance.

SUNLinearSolver SUNSPFGMR(N_Vector y, int pretype, int maxl);

• SUNSPFGMRSetPrecType

This function updates the flag indicating use of preconditioning. Since the FGMRES algorithm is designed to only support right preconditioning, then any of the pretype inputs PREC_LEFT (1), PREC_RIGHT (2), or PREC_BOTH (3) will result in use of PREC_RIGHT; any other integer input will result in the default (no preconditioning).

This routine will return with one of the error codes SUNLS_MEM_NULL (S is NULL) or SUNLS_SUCCESS. int SUNSPFGMRSetPrecType(SUNLinearSolver S, int pretype);

• SUNSPFGMRSetGSType

This function sets the type of Gram-Schmidt orthogonalization to use. Supported values are MODIFIED_GS (1) and CLASSICAL_GS (2). Any other integer input will result in a failure, returning error code SUNLS_ILL_INPUT.

This routine will return with one of the error codes SUNLS_ILL_INPUT (illegal gstype), SUNLS_MEM_NULL (S is NULL), or SUNLS_SUCCESS.

int SUNSPFGMRSetGSType(SUNLinearSolver S, int gstype);

• SUNSPFGMRSetMaxRestarts

This function sets the number of FGMRES restarts to allow. A negative input will result in the default of 0.

This routine will return with one of the error codes SUNLS_MEM_NULL (S is NULL) or SUNLS_SUCCESS.

int SUNSPFGMRSetMaxRestarts(SUNLinearSolver S, int maxrs);

For solvers that include a Fortran interface module, the SUNLINSOL_SPFGMR module also includes the Fortran-callable function FSUNSPFGMRInit(code, pretype, maxl, ier) to initialize this SUNLINSOL_SPFGMR module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); pretype and maxl are the same as for the C function SUNSPFGMR; ier is an error return flag equal to 0 for success and -1 for failure. All of these input arguments should be declared so as to match C type int. This routine must be called after the NVECTOR object has been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassSPFGMRInit(pretype, maxl, ier) initializes this SUNLINSOL_SPFGMR module for solving mass matrix linear systems.

The SUNSPFGMRSetPrecType, SUNSPFGMRSetGSType, and SUNSPFGMRSetMaxRestarts routines also support Fortran interfaces for the system and mass matrix solvers (all arguments should be commensurate with a C int):

```
FSUNSPFGMRSetGSType(code, gstype, ier)
FSUNMassSPFGMRSetGSType(gstype, ier)
FSUNSPFGMRSetPrecType(code, pretype, ier)
FSUNMassSPFGMRSetPrecType(pretype, ier)
FSUNSPFGMRSetMaxRS(code, maxrs, ier)
```

• FSUNMassSPFGMRSetMaxRS(maxrs, ier)

8.11 The SUNLinearSolver_SPBCGS implementation

The SPBCGS (Scaled, Preconditioned, Bi-Conjugate Gradient, Stabilized [37]) implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL_SPBCGS, is an iterative linear solver that is designed to be compatible with any NVECTOR implementation (serial, threaded, parallel, and user-supplied) that supports a minimal subset of operations (N_VClone, N_VDotProd, N_VScale, N_VLinearSum, N_VProd, N_VDiv, and N_VDestroy). Unlike the SPGMR and SPFGMR algorithms, SPBCGS requires a fixed amount of memory that does not increase with the number of allowed iterations.

The $\mathtt{SUNLINSOL_SPBCGS}$ module defines the content field of a $\mathtt{SUNLinearSolver}$ to be the following structure:

```
struct _SUNLinearSolverContent_SPBCGS {
  int maxl;
  int pretype;
  int numiters;
  realtype resnorm;
  long int last_flag;
  ATimesFn ATimes;
  void* ATData;
  PSetupFn Psetup;
  PSolveFn Psolve;
  void* PData;
  N_Vector s1;
  N_Vector s2;
  N_Vector r;
  N_Vector r_star;
  N_Vector p;
  N_Vector q;
  N_Vector u;
  N_Vector Ap;
  N_Vector vtemp;
};
```

These entries of the *content* field contain the following information:

maxl - number of SPBCGS iterations to allow (default is 5),

pretype - flag for type of preconditioning to employ (default is none),

numiters - number of iterations from the most-recent solve,

resnorm - final linear residual norm from the most-recent solve,

last_flag - last error return flag from an internal function,

ATimes - function pointer to perform Av product,

ATData - pointer to structure for ATimes,

Psetup - function pointer to preconditioner setup routine,

Psolve - function pointer to preconditioner solve routine,

PData - pointer to structure for Psetup and Psolve,

s1, s2 - vector pointers for supplied scaling matrices (default is NULL),

r - a NVECTOR which holds the current scaled, preconditioned linear system residual,

r_star - a NVECTOR which holds the initial scaled, preconditioned linear system residual,

p, q, u, Ap, vtemp - NVECTORS used for workspace by the SPBCGS algorithm.

This solver is constructed to perform the following operations:

- During construction all NVECTOR solver data is allocated, with vectors cloned from a template NVECTOR that is input, and default solver parameters are set.
- User-facing "set" routines may be called to modify default solver parameters.
- Additional "set" routines are called by the SUNDIALS solver that interfaces with SUNLINSOL_SPBCGS to supply the ATimes, PSetup, and Psolve function pointers and s1 and s2 scaling vectors.
- In the "initialize" call, the solver parameters are checked for validity.
- In the "setup" call, any non-NULL PSetup function is called. Typically, this is provided by the SUNDIALS solver itself, that translates between the generic PSetup function and the solver-specific routine (solver-supplied or user-supplied).
- In the "solve" call the SPBCGS iteration is performed. This will include scaling and preconditioning if those options have been supplied.

The header file to include when using this module is sunlinsol_spbcgs.h. The SUNLINSOL_SPBCGS module is accessible from all SUNDIALS solvers without linking to the

libsundials_sunlinsolspbcgs module library.

The SUNLINSOL_SPBCGS module defines implementations of all "iterative" linear solver operations listed in Table 8.2:

- SUNLinSolGetType_SPBCGS
- SUNLinSolInitialize_SPBCGS
- SUNLinSolSetATimes_SPBCGS
- SUNLinSolSetPreconditioner_SPBCGS
- SUNLinSolSetScalingVectors_SPBCGS

- SUNLinSolSetup_SPBCGS
- SUNLinSolSolve_SPBCGS
- SUNLinSolNumIters_SPBCGS
- SUNLinSolResNorm_SPBCGS
- SUNLinSolResid_SPBCGS
- SUNLinSolLastFlag_SPBCGS
- SUNLinSolSpace_SPBCGS
- SUNLinSolFree_SPBCGS

The module SUNLINSOL_SPBCGS provides the following additional user-callable routines:

• SUNSPBCGS

This constructor function creates and allocates memory for a SPBCGS SUNLinearSolver. Its arguments are an NVECTOR, the desired type of preconditioning, and the number of linear iterations to allow.

This routine will perform consistency checks to ensure that it is called with a consistent NVECTOR implementation (i.e. that it supplies the requisite vector operations). If y is incompatible, then this routine will return NULL.

A max1 argument that is ≤ 0 will result in the default value (5).

Allowable inputs for pretype are PREC_NONE (0), PREC_LEFT (1), PREC_RIGHT (2) and PREC_BOTH (3); any other integer input will result in the default (no preconditioning). We note that some SUNDIALS solvers are designed to only work with left preconditioning (IDA and IDAS) and others with only right preconditioning (KINSOL). While it is possible to configure a SUNLINSOL_SPBCGS object to use any of the preconditioning options with these solvers, this use mode is not supported and may result in inferior performance.

SUNLinearSolver SUNSPBCGS(N_Vector y, int pretype, int maxl);

SUNSPBCGSSetPrecType

This function updates the type of preconditioning to use. Supported values are PREC_NONE (0), PREC_LEFT (1), PREC_RIGHT (2), and PREC_BOTH (3).

This routine will return with one of the error codes SUNLS_ILL_INPUT (illegal pretype), SUNLS_MEM_NULL (S is NULL), or SUNLS_SUCCESS.

int SUNSPBCGSSetPrecType(SUNLinearSolver S, int pretype);

• SUNSPBCGSSetMax1

This function updates the number of linear solver iterations to allow.

A max1 argument that is ≤ 0 will result in the default value (5).

This routine will return with one of the error codes ${\tt SUNLS_MEM_NULL}$ (S is ${\tt NULL}$) or ${\tt SUNLS_SUCCESS}$.

int SUNSPBCGSSetMaxl(SUNLinearSolver S, int maxl);

For solvers that include a Fortran interface module, the SUNLINSOL_SPBCGS module also includes the Fortran-callable function FSUNSPBCGSInit(code, pretype, maxl, ier) to initialize this SUNLINSOL_SPBCGS module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); pretype and maxl are the same as for the C function SUNSPBCGS; ier is an error return flag equal to 0 for success and -1 for failure. All of these input arguments should be declared so as to match C type int. This routine must be called after the NVECTOR object has been initialized. Additionally, when using ARKODE with a non-identity

mass matrix, the Fortran-callable function FSUNMassSPBCGSInit(pretype, maxl, ier) initializes this SUNLINSOL_SPBCGS module for solving mass matrix linear systems.

The SUNSPBCGSSetPrecType and SUNSPBCGSSetMaxl routines also support Fortran interfaces for the system and mass matrix solvers (all arguments should be commensurate with a C int):

```
• FSUNSPBCGSSetPrecType(code, pretype, ier)
```

- FSUNMassSPBCGSSetPrecType(pretype, ier)
- FSUNSPBCGSSetMaxl(code, maxl, ier)
- FSUNMassSPBCGSSetMaxl(maxl, ier)

struct _SUNLinearSolverContent_SPTFQMR {

8.12 The SUNLinearSolver_SPTFQMR implementation

The SPTFQMR (Scaled, Preconditioned, Transpose-Free Quasi-Minimum Residual [19]) implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL_SPTFQMR, is an iterative linear solver that is designed to be compatible with any NVECTOR implementation (serial, threaded, parallel, and user-supplied) that supports a minimal subset of operations (N_VClone, N_VDotProd, N_VScale, N_VLinearSum, N_VProd, N_VConst, N_VDiv, and N_VDestroy). Unlike the SPGMR and SPFGMR algorithms, SPTFQMR requires a fixed amount of memory that does not increase with the number of allowed iterations.

The SUNLINSOL_SPTFQMR module defines the *content* field of a SUNLinearSolver to be the following structure:

```
int maxl;
  int pretype;
  int numiters;
  realtype resnorm;
  long int last_flag;
  ATimesFn ATimes;
  void* ATData;
  PSetupFn Psetup;
  PSolveFn Psolve;
  void* PData;
  N_Vector s1;
  N_Vector s2;
  N_Vector r_star;
  N_Vector q;
  N_Vector d;
  N_Vector v;
  N_Vector p;
  N_Vector *r;
  N_Vector u;
  N_Vector vtemp1;
  N_Vector vtemp2;
  N_Vector vtemp3;
};
These entries of the content field contain the following information:
maxl - number of TFQMR iterations to allow (default is 5),
pretype - flag for type of preconditioning to employ (default is none),
numiters - number of iterations from the most-recent solve,
```

resnorm - final linear residual norm from the most-recent solve,

last_flag - last error return flag from an internal function,

ATimes - function pointer to perform Av product,

ATData - pointer to structure for ATimes,

Psetup - function pointer to preconditioner setup routine,

Psolve - function pointer to preconditioner solve routine,

PData - pointer to structure for Psetup and Psolve,

s1, s2 - vector pointers for supplied scaling matrices (default is NULL),

r_star - a NVECTOR which holds the initial scaled, preconditioned linear system residual,

q, d, v, p, u - NVECTORS used for workspace by the SPTFQMR algorithm,

r - array of two NVECTORS used for workspace within the SPTFQMR algorithm,

vtemp1, vtemp2, vtemp3 - temporary vector storage.

This solver is constructed to perform the following operations:

- During construction all NVECTOR solver data is allocated, with vectors cloned from a template NVECTOR that is input, and default solver parameters are set.
- User-facing "set" routines may be called to modify default solver parameters.
- Additional "set" routines are called by the SUNDIALS solver that interfaces with SUNLINSOL_SPTFQMR to supply the ATimes, PSetup, and Psolve function pointers and s1 and s2 scaling vectors.
- In the "initialize" call, the solver parameters are checked for validity.
- In the "setup" call, any non-NULL PSetup function is called. Typically, this is provided by the SUNDIALS solver itself, that translates between the generic PSetup function and the solver-specific routine (solver-supplied or user-supplied).
- In the "solve" call the TFQMR iteration is performed. This will include scaling and preconditioning if those options have been supplied.

The header file to include when using this module is sunlinsol/sunlinsol_sptfqmr.h. The SUNLINSOL_SPTFQMR module is accessible from all SUNDIALS solvers without linking to the

libsundials_sunlinsolsptfqmr module library.

The SUNLINSOL_SPTFQMR module defines implementations of all "iterative" linear solver operations listed in Table 8.2:

- SUNLinSolGetType_SPTFQMR
- SUNLinSolInitialize_SPTFQMR
- SUNLinSolSetATimes_SPTFQMR
- SUNLinSolSetPreconditioner_SPTFQMR
- SUNLinSolSetScalingVectors_SPTFQMR
- SUNLinSolSetup_SPTFQMR
- $\bullet \ {\tt SUNLinSolSolve_SPTFQMR} \\$
- SUNLinSolNumIters_SPTFQMR

- SUNLinSolResNorm_SPTFQMR
- SUNLinSolResid_SPTFQMR
- SUNLinSolLastFlag_SPTFQMR
- SUNLinSolSpace_SPTFQMR
- SUNLinSolFree_SPTFQMR

The module SUNLINSOL_SPTFQMR provides the following additional user-callable routines:

• SUNSPTFQMR

This constructor function creates and allocates memory for a SPTFQMR SUNLinearSolver. Its arguments are an NVECTOR, the desired type of preconditioning, and the number of linear iterations to allow.

This routine will perform consistency checks to ensure that it is called with a consistent NVECTOR implementation (i.e. that it supplies the requisite vector operations). If y is incompatible, then this routine will return NULL.

A max1 argument that is ≤ 0 will result in the default value (5).

Allowable inputs for pretype are PREC_NONE (0), PREC_LEFT (1), PREC_RIGHT (2) and PREC_BOTH (3); any other integer input will result in the default (no preconditioning). We note that some SUNDIALS solvers are designed to only work with left preconditioning (IDA and IDAS) and others with only right preconditioning (KINSOL). While it is possible to configure a SUNLINSOL_SPTFQMR object to use any of the preconditioning options with these solvers, this use mode is not supported and may result in inferior performance.

SUNLinearSolver SUNSPTFQMR(N_Vector y, int pretype, int maxl);

• SUNSPTFQMRSetPrecType

This function updates the type of preconditioning to use. Supported values are PREC_NONE (0), PREC_LEFT (1), PREC_RIGHT (2), and PREC_BOTH (3).

This routine will return with one of the error codes SUNLS_ILL_INPUT (illegal pretype), SUNLS_MEM_NULL (S is NULL), or SUNLS_SUCCESS.

int SUNSPTFQMRSetPrecType(SUNLinearSolver S, int pretype);

• SUNSPTFQMRSetMax1

This function updates the number of linear solver iterations to allow.

A max1 argument that is ≤ 0 will result in the default value (5).

This routine will return with one of the error codes ${\tt SUNLS_MEM_NULL} \ ({\tt S} \ {\tt is} \ {\tt NULL}) \ {\tt or} \ {\tt SUNLS_SUCCESS}.$

int SUNSPTFQMRSetMaxl(SUNLinearSolver S, int maxl);

For solvers that include a Fortran interface module, the SUNLINSOL_SPTFQMR module also includes the Fortran-callable function FSUNSPTFQMRInit(code, pretype, maxl, ier) to initialize this SUNLINSOL_SPTFQMR module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); pretype and maxl are the same as for the C function SUNSPTFQMR; ier is an error return flag equal to 0 for success and -1 for failure. All of these input arguments should be declared so as to match C type int. This routine must be called after the NVECTOR object has been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassSPTFQMRInit(pretype, maxl, ier) initializes this SUNLINSOL_SPTFQMR module for solving mass matrix linear systems.

The SUNSPTFQMRSetPrecType and SUNSPTFQMRSetMaxl routines also support Fortran interfaces for the system and mass matrix solvers (all arguments should be commensurate with a C int):

• FSUNSPTFQMRSetPrecType(code, pretype, ier)

- FSUNMassSPTFQMRSetPrecType(pretype, ier)
- FSUNSPTFQMRSetMaxl(code, maxl, ier)
- FSUNMassSPTFQMRSetMaxl(maxl, ier)

8.13 The SUNLinearSolver_PCG implementation

The PCG (Preconditioned Conjugate Gradient [20]) implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL_PCG, is an iterative linear solver that is designed to be compatible with any NVECTOR implementation (serial, threaded, parallel, and user-supplied) that supports a minimal subset of operations (N_VClone, N_VDotProd, N_VScale, N_VLinearSum, N_VProd, and N_VDestroy). Unlike the SPGMR and SPFGMR algorithms, PCG requires a fixed amount of memory that does not increase with the number of allowed iterations.

Unlike all of the other iterative linear solvers supplied with SUNDIALS, PCG should only be used on symmetric linear systems (e.g. mass matrix linear systems encountered in ARKODE). As a result, the explanation of the role of scaling and preconditioning matrices given in general must be modified in this scenario. The PCG algorithm solves a linear system Ax = b where A is a symmetric $(A^T = A)$, real-valued matrix. Preconditioning is allowed, and is applied in a symmetric fashion on both the right and left. Scaling is also allowed and is applied symmetrically. We denote the preconditioner and scaling matrices as follows:

- P is the preconditioner (assumed symmetric),
- \bullet S is a diagonal matrix of scale factors.

The matrices A and P are not required explicitly; only routines that provide A and P^{-1} as operators are required. The diagonal of the matrix S is held in a single NVECTOR, supplied by the user.

In this notation, PCG applies the underlying CG algorithm to the equivalent transformed system

$$\tilde{A}\tilde{x} = \tilde{b} \tag{8.3}$$

where

$$\tilde{A} = SP^{-1}AP^{-1}S,$$

$$\tilde{b} = SP^{-1}b,$$

$$\tilde{x} = S^{-1}Px.$$
(8.4)

The scaling matrix must be chosen so that the vectors $SP^{-1}b$ and $S^{-1}Px$ have dimensionless components.

The stopping test for the PCG iterations is on the L2 norm of the scaled preconditioned residual:

$$\begin{split} &\|\tilde{b} - \tilde{A}\tilde{x}\|_2 < \delta \\ \Leftrightarrow & \\ &\|SP^{-1}b - SP^{-1}Ax\|_2 < \delta \\ \Leftrightarrow & \\ &\|P^{-1}b - P^{-1}Ax\|_S < \delta \end{split}$$

where $||v||_S = \sqrt{v^T S^T S v}$, with an input tolerance δ .

The SUNLINSOL_PCG module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_PCG {
  int maxl;
  int pretype;
```

```
int numiters;
  realtype resnorm;
  long int last_flag;
  ATimesFn ATimes;
  void* ATData;
  PSetupFn Psetup;
  PSolveFn Psolve;
  void* PData;
  N_Vector s;
  N_Vector r;
  N_Vector p;
  N_Vector z;
  N_Vector Ap;
};
These entries of the content field contain the following information:
maxl - number of PCG iterations to allow (default is 5),
pretype - flag for use of preconditioning (default is none),
numiters - number of iterations from the most-recent solve,
resnorm - final linear residual norm from the most-recent solve.
last_flag - last error return flag from an internal function,
ATimes - function pointer to perform Av product,
ATData - pointer to structure for ATimes,
Psetup - function pointer to preconditioner setup routine,
Psolve - function pointer to preconditioner solve routine,
PData - pointer to structure for Psetup and Psolve,
s - vector pointer for supplied scaling matrix (default is NULL),
r - a NVECTOR which holds the preconditioned linear system residual,
```

p, z, Ap - NVECTORS used for workspace by the PCG algorithm.

This solver is constructed to perform the following operations:

- During construction all NVECTOR solver data is allocated, with vectors cloned from a template NVECTOR that is input, and default solver parameters are set.
- User-facing "set" routines may be called to modify default solver parameters.
- Additional "set" routines are called by the SUNDIALS solver that interfaces with SUNLINSOL_PCG to supply the ATimes, PSetup, and Psolve function pointers and s scaling vector.
- In the "initialize" call, the solver parameters are checked for validity.
- In the "setup" call, any non-NULL PSetup function is called. Typically, this is provided by the SUNDIALS solver itself, that translates between the generic PSetup function and the solver-specific routine (solver-supplied or user-supplied).
- In the "solve" call the PCG iteration is performed. This will include scaling and preconditioning if those options have been supplied.

The header file to include when using this module is sunlinsol_pcg.h. The SUNLINSOL_PCG module is accessible from all SUNDIALS solvers without linking to the

libsundials_sunlinsolpcg module library.

The SUNLINSOL_PCG module defines implementations of all "iterative" linear solver operations listed in Table 8.2:

- SUNLinSolGetType_PCG
- SUNLinSolInitialize_PCG
- SUNLinSolSetATimes_PCG
- SUNLinSolSetPreconditioner_PCG
- SUNLinSolSetScalingVectors_PCG since PCG only supports symmetric scaling, the second NVECTOR argument to this function is ignored
- SUNLinSolSetup_PCG
- SUNLinSolSolve_PCG
- SUNLinSolNumIters_PCG
- SUNLinSolResNorm_PCG
- SUNLinSolResid_PCG
- SUNLinSolLastFlag_PCG
- SUNLinSolSpace_PCG
- SUNLinSolFree_PCG

The module SUNLINSOL_PCG provides the following additional user-callable routines:

• SUNPCG

This constructor function creates and allocates memory for a PCG SUNLinearSolver. Its arguments are an NVECTOR, a flag indicating to use preconditioning, and the number of linear iterations to allow.

This routine will perform consistency checks to ensure that it is called with a consistent NVECTOR implementation (i.e. that it supplies the requisite vector operations). If y is incompatible then this routine will return NULL.

A max1 argument that is ≤ 0 will result in the default value (5).

Since the PCG algorithm is designed to only support symmetric preconditioning, then any of the pretype inputs PREC_LEFT (1), PREC_RIGHT (2), or PREC_BOTH (3) will result in use of the symmetric preconditioner; any other integer input will result in the default (no preconditioning). Although some SUNDIALS solvers are designed to only work with left preconditioning (IDA and IDAS) and others with only right preconditioning (KINSOL), PCG should *only* be used with these packages when the linear systems are known to be *symmetric*. Since the scaling of matrix rows and columns must be identical in a symmetric matrix, symmetric preconditioning should work appropriately even for packages designed with one-sided preconditioning in mind.

SUNLinearSolver SUNPCG(N_Vector y, int pretype, int maxl);

• SUNPCGSetPrecType

This function updates the flag indicating use of preconditioning. As above, any one of the input values, PREC_LEFT (1), PREC_RIGHT (2), or PREC_BOTH (3) will enable preconditioning; PREC_NONE (0) disables preconditioning.

This routine will return with one of the error codes SUNLS_ILL_INPUT (illegal pretype), SUNLS_MEM_NULL (S is NULL), or SUNLS_SUCCESS.

int SUNPCGSetPrecType(SUNLinearSolver S, int pretype);

• SUNPCGSetMax1

This function updates the number of linear solver iterations to allow.

A max1 argument that is ≤ 0 will result in the default value (5).

This routine will return with one of the error codes SUNLS_MEM_NULL (S is NULL) or SUNLS_SUCCESS. int SUNPCGSetMaxl(SUNLinearSolver S, int maxl);

For solvers that include a Fortran interface module, the SUNLINSOL_PCG module also includes the Fortran-callable function FSUNPCGInit(code, pretype, maxl, ier) to initialize this SUNLINSOL_PCG module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); pretype and maxl are the same as for the C function SUNPCG; ier is an error return flag equal to 0 for success and -1 for failure. All of these input arguments should be declared so as to match C type int. This routine must be called after the NVECTOR object has been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassPCGInit(pretype, maxl, ier) initializes this SUNLINSOL_PCG module for solving mass matrix linear systems.

The SUNPCGSetPrecType and SUNPCGSetMaxl routines also support Fortran interfaces for the system and mass matrix solvers (all arguments should be commensurate with a C int):

- FSUNPCGSetPrecType(code, pretype, ier)
- FSUNMassPCGSetPrecType(pretype, ier)
- FSUNPCGSetMaxl(code, maxl, ier)
- FSUNMassPCGSetMaxl(maxl, ier)

8.14 SUNLinearSolver Examples

There are SUNLinearSolver examples that may be installed for each implementation; these make use of the functions in test_sunlinsol.c. These example functions show simple usage of the SUNLinearSolver family of functions. The inputs to the examples depend on the linear solver type, and are output to stdout if the example is run without the appropriate number of command-line arguments.

The following is a list of the example functions in test_sunlinsol.c:

- Test_SUNLinSolGetType: Verifies the returned solver type against the value that should be returned.
- Test_SUNLinSolInitialize: Verifies that SUNLinSolInitialize can be called and returns successfully.
- Test_SUNLinSolSetup: Verifies that SUNLinSolSetup can be called and returns successfully.
- Test_SUNLinSolSolve: Given a SUNMATRIX object A, NVECTOR objects x and b (where Ax = b) and a desired solution tolerance tol, this routine clones x into a new vector y, calls SUNLinSolSolve to fill y as the solution to Ay = b (to the input tolerance), verifies that each entry in x and y match to within 10*tol, and overwrites x with y prior to returning (in case the calling routine would like to investigate further).
- Test_SUNLinSolSetATimes (iterative solvers only): Verifies that SUNLinSolSetATimes can be called and returns successfully.
- Test_SUNLinSolSetPreconditioner (iterative solvers only): Verifies that SUNLinSolSetPreconditioner can be called and returns successfully.
- Test_SUNLinSolSetScalingVectors (iterative solvers only): Verifies that SUNLinSolSetScalingVectors can be called and returns successfully.

- Test_SUNLinSolLastFlag: Verifies that SUNLinSolLastFlag can be called, and outputs the result to stdout.
- Test_SUNLinSolNumIters (iterative solvers only): Verifies that SUNLinSolNumIters can be called, and outputs the result to stdout.
- Test_SUNLinSolResNorm (iterative solvers only): Verifies that SUNLinSolResNorm can be called, and that the result is non-negative.
- Test_SUNLinSolResid (iterative solvers only): Verifies that SUNLinSolResid can be called.
- Test_SUNLinSolSpace verifies that SUNLinSolSpace can be called, and outputs the results to stdout.

We'll note that these tests should be performed in a particular order. For either direct or iterative linear solvers, Test_SUNLinSolInitialize must be called before Test_SUNLinSolSetup, which must be called before Test_SUNLinSolSolve. Additionally, for iterative linear solvers Test_SUNLinSolSetATimes, Test_SUNLinSolSetPreconditioner and Test_SUNLinSolSetScalingVectors should be called before Test_SUNLinSolInitialize; similarly Test_SUNLinSolNumIters, Test_SUNLinSolResNorm and Test_SUNLinSolResid should be called after Test_SUNLinSolSolve. These are called in the appropriate order in all of the example problems.

8.15 SUNLinearSolver functions used by CVODE

In Table 8.5, we list the linear solver functions in the SUNLINSOL module used within the CVODE package. The table also shows, for each function, which of the code modules uses the function. In general, the main CVODE integrator considers three categories of linear solvers, direct, iterative and custom, with interfaces accessible in the CVODE header files cvode/cvode_direct.h (CVDLS), cvode/cvode_spils.h (CVSPILS) and cvode/cvode_customls.h (CVCLS), respectively. Hence, the table columns reference the use of SUNLINSOL functions by each of these solver interfaces.

As with the SUNMATRIX module, we emphasize that the CVODE user does not need to know detailed usage of linear solver functions by the CVODE code modules in order to use CVODE. The information is presented as an implementation detail for the interested reader.

	CVDLS	CVSPILS	CVCLS
SUNLinSolGetType	√	√	†
SUNLinSolSetATimes		√	†
SUNLinSolSetPreconditioner		√	†
SUNLinSolSetScalingVectors		√	†
SUNLinSolInitialize	√	√	√
SUNLinSolSetup	√	√	√
SUNLinSolSolve	√	√	√
SUNLinSolNumIters		√	†
SUNLinSolResNorm		√	†
SUNLinSolResid		√	†
SUNLinSolLastFlag			
SUNLinSolFree	√	√	√
SUNLinSolSpace	†	†	†

Table 8.5: List of linear solver functions usage by CVODE code modules

The linear solver functions listed in Table 8.2 with a † symbol are optionally used, in that these are only called if they are implemented in the SUNLINSOL module that is being used (i.e. their function

pointers are non-NULL). Also, although CVODE does not call SUNLinSolLastFlag directly, this routine is available for users to query linear solver issues directly.

Chapter 9

Description of the SUNNonlinearSolver module

SUNDIALS time integration packages are written in terms of generic nonlinear solver operations defined by the SUNNONLINSOL API and implemented by a particular SUNNONLINSOL module of type SUNNonlinearSolver. Users can supply their own SUNNONLINSOL module, or use one of the modules provided with SUNDIALS.

The time integrators in SUNDIALS specify a default nonlinear solver module and as such this chapter is intended for users that wish to use a non-default nonlinear solver module or would like to provide their own nonlinear solver implementation. Users interested in using a non-default solver module may skip the description of the SUNNONLINSOL API in section 9.1 and proceeded to the subsequent sections in this chapter that describe the SUNNONLINSOL modules provided with SUNDIALS.

For users interested in providing their own Sunnonlinsol module, the following section presents the Sunnonlinsol API and its implementation beginning with the definition of Sunnonlinsol functions in sections 9.1.1 - 9.1.3. This is followed by the definition of functions supplied to a nonlinear solver implementation in section 9.1.4. A table of nonlinear solver return codes is given in section 9.1.5. The SunnonlinearSolver type and the generic Sunnonlinsol module are defined in section 9.1.6. Finally, section 9.1.7 lists the requirements for supplying a custom Sunnonlinsol module. Users wishing to supply their own Sunnonlinsol module are encouraged to use the Sunnonlinear solver modules.

9.1 The SUNNonlinear Solver API

The SUNNONLINSOL API defines several nonlinear solver operations that enable SUNDIALS integrators to utilize any SUNNONLINSOL implementation that provides the required functions. These functions can be divided into three categories. The first are the core nonlinear solver functions. The second group of functions consists of set routines to supply the nonlinear solver with functions provided by the SUNDIALS time integrators and to modify solver parameters. The final group consists of get routines for retrieving nonlinear solver statistics. All of these functions are defined in the header file sundials_nonlinearsolver.h.

9.1.1 SUNNonlinearSolver core functions

The core nonlinear solver functions consist of two required functions to get the nonlinear solver type (SUNNonlinsSolGetType) and solve the nonlinear system (SUNNonlinSolSolve). The remaining three functions for nonlinear solver initialization (SUNNonlinSolInitialization), setup (SUNNonlinSolSetup), and destruction (SUNNonlinSolFree) are optional.

SUNNonlinSolGetType

Call type = SUNNonlinSolGetType(NLS);

Description The required function SUNNonlinSolGetType returns nonlinear solver type.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object.

Return value The return value type (of type int) will be one of the following:

SUNNONLINEARSOLVER_ROOTFIND 0, the SUNNONLINSOL module solves F(y) = 0. SUNNONLINEARSOLVER_FIXEDPOINT 1, the SUNNONLINSOL module solves G(y) = y.

SUNNonlinSolInitialize

Call retval = SUNNonlinSolInitialize(NLS);

Description The optional function SUNNonlinSolInitialize performs nonlinear solver initialization

and may perform any necessary memory allocations.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object.

Return value The return value retval (of type int) is zero for a successful call and a negative value

for a failure.

Notes It is assumed all solver-specific options have been set prior to calling

SUNNonlinSolInitialize. SUNNONLINSOL implementations that do not require initial-

ization may set this operation to NULL.

SUNNonlinSolSetup

Call retval = SUNNonlinSolSetup(NLS, y, mem);

Description The optional function SUNNonlinSolSetup performs any solver setup needed for a non-

linear solve.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object.

y (N_Vector) the initial iteration passed to the nonlinear solver.

mem (void *) the SUNDIALS integrator memory structure.

Return value The return value retval (of type int) is zero for a successful call and a negative value

for a failure.

Notes SUNDIALS integrators call SUNonlinSolSetup before each step attempt. SUNNONLINSOL

implementations that do not require setup may set this operation to NULL.

SUNNonlinSolSolve

Call retval = SUNNonlinSolSolve(NLS, y0, y, w, tol, callLSetup, mem);

Description The required function SUNNonlinSolSolve solves the nonlinear system F(y) = 0 or

G(y) = y.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object.

y0 (N_Vector) the initial iterate for the nonlinear solve. This must remain

unchanged throughout the solution process.

y (N_Vector) the solution to the nonlinear system.

w (N_Vector) the solution error weight vector used for computing weighted

error norms.

tol (realtype) the requested solution tolerance in the weighted root-mean-

squared norm.

callLSetup (booleantype) a flag indicating that the integrator recommends for the

linear solver setup function to be called.

mem (void *) the SUNDIALS integrator memory structure.

Return value The return value retval (of type int) is zero for a successul solve, a positive value for a recoverable error, and a negative value for an unrecoverable error.

SUNNonlinSolFree

Call retval = SUNNonlinSolFree(NLS);

Description The optional function SUNNonlinSolFree frees any memory allocated by the nonlinear

solver.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object.

Return value The return value retval (of type int) should be zero for a successful call, and a negative

value for a failure. SUNNONLINSOL implementations that do not allocate data may set

this operation to NULL.

9.1.2 SUNNonlinearSolver set functions

The following set functions are used to supply nonlinear solver modules with functions defined by the SUNDIALS integrators and to modify solver parameters. Only the routine for setting the nonlinear system defining function (SUNNonlinSolSetSysFn is required. All other set functions are optional.

SUNNonlinSolSetSysFn

Call retval = SUNNonlinSolSetSysFn(NLS, SysFn);

Description The required function SUNNonlinSolSetSysFn is used to provide the nonlinear solver

with the function defining the nonlinear system. This is the function F(y) in F(y) = 0

for SUNNONLINEARSOLVER_ROOTFIND modules or G(y) in G(y) = y for

SUNNONLINEARSOLVER_FIXEDPOINT modules.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object.

SysFn (SUNNonlinSolSysFn) the function defining the nonlinear system. See section

9.1.4 for the definition of SUNNonlinSolSysFn.

Return value The return value retval (of type int) should be zero for a successful call, and a negative

value for a failure.

SUNNonlinSolSetLSetupFn

Call retval = SUNNonlinSolSetLSetupFn(NLS, LSetupFn);

Description The optional function SUNNonlinSollSetupFn is called by SUNDIALS integrators to

provide the nonlinear solver with access to its linear solver setup function.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object.

LSetupFn (SUNNonlinSolLSetupFn) a wrapper function to the SUNDIALS integrator's

linear solver setup function. See section 9.1.4 for the definition of

SUNNonlinLSetupFn.

Return value The return value retval (of type int) should be zero for a successful call, and a negative

value for a failure.

Notes The SUNNonlinLSetupFn function sets up the linear system Ax = b where $A = \frac{\partial F}{\partial y}$ is the linearization of the nonlinear residual function F(y) = 0 (when using SUNLINSOL direct linear solvers) or calls the user-defined preconditioner setup function (when using SUNLINSOL iterative linear solvers). SUNNONLINSOL implementations that do not require solving this system, do not utilize SUNLINSOL linear solvers, or use SUNLINSOL linear solvers that do not require setup may set this operation to NULL.

SUNNonlinSolSetLSolveFn

Call retval = SUNNonlinSolSetLSolveFn(NLS, LSolveFn);

Description The optional function SUNNonlinSolSetLSolveFn is called by SUNDIALS integrators to

provide the nonlinear solver with access to its linear solver solve function.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object

LSolveFn (SUNNonlinSolLSolveFn) a wrapper function to the SUNDIALS integrator's

linear solver solve function. See section 9.1.4 for the definition of

SUNNonlinSolLSolveFn.

Return value The return value retval (of type int) should be zero for a successful call, and a negative

value for a failure.

Notes The SUNNonlinLSolveFn function solves the linear system Ax = b where $A = \frac{\partial F}{\partial y}$ is the

linearization of the nonlinear residual function F(y) = 0. SUNNONLINSOL implementations that do not require solving this system or do not use SUNLINSOL linear solvers may

set this operation to NULL.

SUNNonlinSolSetConvTestFn

Call retval = SUNNonlinSolSetConvTestFn(NLS, CTestFn);

Description The optional function SUNNonlinSolSetConvTestFn is used to provide the nonlinear

solver with a function for determining if the nonlinear solver iteration has converged. This is typically called by SUNDIALS integrators to define their nonlinear convergence

criteria, but may be replaced by the user.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object.

CTestFn (SUNNonlineSolConvTestFn) a SUNDIALS integrator's nonlinear solver conver-

gence test function. See section 9.1.4 for the definition of

SUNNonlinSolConvTestFn.

Return value The return value retval (of type int) should be zero for a successful call, and a negative

value for a failure.

Notes SUNNONLINSOL implementations utilizing their own convergence test criteria may set

this function to NULL.

SUNNonlinSolSetMaxIters

Call retval = SUNNonlinSolSetMaxIters(NLS, maxiters);

Description The optional function SUNNonlinSolSetMaxIters sets the maximum number of non-

linear solver iterations. This is typically called by SUNDIALS integrators to define their

default iteration limit, but may be adjusted by the user.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object.

maxiters (int) the maximum number of nonlinear iterations.

Return value The return value retval (of type int) should be zero for a successful call, and a negative

value for a failure (e.g., maxiters < 1).

9.1.3 SUNNonlinearSolver get functions

The following get functions allow SUNDIALS integrators to retrieve nonlinear solver statistics. The routine for getting the current total number of iterations (SUNNonlinSolGetNumIters is optional. The routine for getting the current nonlinear solver iteration (SUNNonlinSolGetCurIter) is required when using the convergence test provided by the SUNDIALS integrator or when using a SUNLINSOL spils linear solver otherwise, SUNNonlinSolGetCurIter is optional.

SUNNonlinSolGetNumIters

Call retval = SUNNonlinSolGetNumIters(NLS, numiters);

Description The optional function SUNNonlinSolGetNumIters returns the total number of nonlin-

ear solver iterations. This is typically called by the SUNDIALS integrator to store the

nonlinear solver statistics, but may also be called by the user.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object

numiters (long int*) the total number of nonlinear solver iterations.

Return value The return value retval (of type int) should be zero for a successful call, and a negative

value for a failure.

SUNNonlinSolGetCurIter

Call retval = SUNNonlinSolGetCurIter(NLS, iter);

Description The function SUNNonlinSolGetCurIter returns the iteration index of the current non-

linear solve. This function is required when using Sundials integrator-provided conver-

gence tests and optional for user supplied convergence test functions.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object

iter (int*) the nonlinear solver iteration in the current solve starting from zero.

Return value The return value retval (of type int) should be zero for a successful call, and a negative

value for a failure.

9.1.4 Functions provided by SUNDIALS integrators

To interface with SUNNONLINSOL modules, the SUNDIALS integrators supply a variety of routines for evaluating the nonlinear system, calling the SUNLINSOL setup and solve functions, and testing the nonlinear iteration for convergence. These integrator-provided routines translate between the user-supplied ODE or DAE systems and the generic interfaces to the nonlinear or linear systems of equations that result in their solution. The types for functions provided to a SUNNONLINSOL module are defined in the header file sundials/sundials_nonlinearsolver.h, and are described below.

SUNNonlinSolSysFn

Definition typedef int (*SUNNonlinSolSysFn)(N_Vector y, N_Vector F, void* mem);

Purpose These functions evaluate the nonlinear system F(y) for SUNNONLINEARSOLVER_ROOTFIND

type modules or G(y) for Sunnonlinear Solver_fixedpoint type modules. Memory for F must by be allocated prior to calling this function. The vector y must be left

unchanged.

Arguments y is the state vector at which the nonlinear system should be evaluated.

F is the output vector containing F(y) or G(y), depending on the solver type.

mem is the SUNDIALS integrator memory structure.

Return value The return value retval (of type int) is zero for a successul solve, a positive value for a recoverable error, and a negative value for an unrecoverable error.

SUNNonlinSolLSetupFn

Definition typedef int (*SUNNonlinSolLSetupFn)(N_Vector y, N_Vector F,

booleantype jbad,

booleantype* jcur, void* mem);

Purpose These functions are wrappers to the SUNDIALS integrator's function for setting up linear

solves with SUNLINSOL modules.

Arguments y is the state vector at which the linear system should be setup.

F is the value of the nonlinear system function at y.

jbad is an input indicating whether the nonlinear solver believes that A has gone stale (SUNTRUE) or not (SUNFALSE).

jcur is an output indicating whether the routine has updated the Jacobian A (SUNTRUE) or not (SUNFALSE).

mem is the SUNDIALS integrator memory structure.

Return value The return value retval (of type int) is zero for a successul solve, a positive value for a recoverable error, and a negative value for an unrecoverable error.

Notes

The SUNNonlinLSetupFn function sets up the linear system Ax = b where $A = \frac{\partial F}{\partial y}$ is the linearization of the nonlinear residual function F(y) = 0 (when using SUNLINSOL direct linear solvers) or calls the user-defined preconditioner setup function (when using SUNLINSOL iterative linear solvers). SUNNONLINSOL implementations that do not require solving this system, do not utilize SUNLINSOL linear solvers, or use SUNLINSOL linear solvers that do not require setup may ignore these functions.

SUNNonlinSolLSolveFn

Definition typedef int (*SUNNonlinSolLSolveFn)(N_Vector y, N_Vector b, void* mem);

Purpose These functions are wrappers to the SUNDIALS integrator's function for solving linear systems with SUNLINSOL modules.

Arguments y is the input vector containing the current nonlinear iteration.

b contains the right-hand side vector for the linear solve on input and the solution to the linear system on output.

mem is the SUNDIALS integrator memory structure.

Return value The return value retval (of type int) is zero for a successul solve, a positive value for a recoverable error, and a negative value for an unrecoverable error.

Notes

The SUNNonlinLSolveFn function solves the linear system Ax = b where $A = \frac{\partial F}{\partial y}$ is the linearization of the nonlinear residual function F(y) = 0. SUNNONLINSOL implementations that do not require solving this system or do not use SUNLINSOL linear solvers may ignore these functions.

SUNNonlinSolConvTestFn

Definition typedef int (*SUNNonlinSolConvTestFn)(SUNNonlinearSolver NLS, N_Vector y, N_Vector del, realtype tol, N_Vector ewt, void* mem);

Purpose These functions are SUNDIALS integrator-specific convergence tests for nonlinear solvers and are typically supplied by each SUNDIALS integrator, but users may supply custom problem-specific versions as desired.

Arguments NLS is the SUNNONLINSOL object.

y is the current nonlinear iterate.

del is the difference between the current and prior nonlinear iterates.

tol is the nonlinear solver tolerance.

ewt is the weight vector used in computing weighted norms.

mem is the SUNDIALS integrator memory structure.

Return value The return value of this routine will be a negative value if an unrecoverable error occurred or one of the following:

SUN_NLS_SUCCESS the iteration is converged.

SUN_NLS_CONTINUE the iteration has not converged, keep iterating.
SUN_NLS_CONV_RECVR the iteration appears to be diverging, try to recover.

Notes

The tolerance passed to this routine by SUNDIALS integrators is the tolerance in a weighted root-mean-squared norm with error weight vector ewt. SUNNONLINSOL modules utilizing their own convergence criteria may ignore these functions.

9.1.5 SUNNonlinearSolver return codes

The functions provided to SUNNONLINSOL modules by each SUNDIALS integrator, and functions within the SUNDIALS-provided SUNNONLINSOL implementations utilize a common set of return codes, shown below in Table 9.1. Here, negative values correspond to non-recoverable failures, positive values to recoverable failures, and zero to a successful call.

Table 9.1. Description of the soundiffication ver feturi codes			
Name	Value	Description	
SUN_NLS_SUCCESS	0	successful call or converged solve	
SUN_NLS_CONTINUE	1	the nonlinear solver is not converged, keep iterating	
SUN_NLS_CONV_RECVR	2	the nonlinear solver appears to be diverging, try to recover	
SUN_NLS_MEM_NULL	-1	a memory argument is NULL	
SUN_NLS_MEM_FAIL	-2	a memory access or allocation failed	
SUN_NLS_ILL_INPUT	-3	an illegal input option was provided	

Table 9.1: Description of the SUNNonlinearSolver return codes

9.1.6 The generic SUNNonlinearSolver module

SUNDIALS integrators interact with specific SUNNONLINSOL implementations through the generic SUNNONLINSOL module on which all other SUNNONLINSOL implementations are built. The SUNNonlinearSolver type is a pointer to a structure containing an implementation-dependent *content* field and an *ops* field. The type SUNNonlinearSolver is defined as follows:

```
typedef struct _generic_SUNNonlinearSolver *SUNNonlinearSolver;
struct _generic_SUNNonlinearSolver {
  void *content;
  struct _generic_SUNNonlinearSolver_Ops *ops;
}:
```

where the _generic_SUNNonlinearSolver_Ops structure is a list of pointers to the various actual non-linear solver operations provided by a specific implementation. The _generic_SUNNonlinearSolver_Ops structure is defined as

```
struct _generic_SUNNonlinearSolver_Ops {
  SUNNonlinearSolver_Type (*gettype)(SUNNonlinearSolver);
                           (*initialize)(SUNNonlinearSolver);
  int
  int
                           (*setup)(SUNNonlinearSolver, N_Vector, void*);
                           (*solve)(SUNNonlinearSolver, N_Vector, N_Vector,
  int
                                    N_Vector, realtype, booleantype, void*);
                           (*free)(SUNNonlinearSolver);
  int
                           (*setsysfn)(SUNNonlinearSolver, SUNNonlinSolSysFn);
  int
  int
                           (*setlsetupfn)(SUNNonlinearSolver, SUNNonlinSolLSetupFn);
                           (*setlsolvefn)(SUNNonlinearSolver, SUNNonlinSolLSolveFn);
  int
  int
                           (*setctestfn)(SUNNonlinearSolver, SUNNonlinSolConvTestFn);
  int
                           (*setmaxiters)(SUNNonlinearSolver, int);
```

```
int (*getnumiters)(SUNNonlinearSolver, long int*);
int (*getcuriter)(SUNNonlinearSolver, int*);
};
```

The generic SUNNONLINSOL module defines and implements the nonlinear solver operations defined in Sections 9.1.1 - 9.1.3. These routines are in fact only wrappers to the nonlinear solver operations provided by a particular SUNNONLINSOL implementation, which are accessed through the ops field of the SUNNonlinearSolver structure. To illustrate this point we show below the implementation of a typical nonlinear solver operation from the generic SUNNONLINSOL module, namely SUNNonlinSolSolve, which solves the nonlinear system and returns a flag denoting a successful or failed solve:

9.1.7 Implementing a Custom SUNNonlinear Solver Module

A SUNNONLINSOL implementation must do the following:

- 1. Specify the content of the SUNNONLINSOL module.
- 2. Define and implement the required nonlinear solver operations defined in Sections 9.1.1 9.1.3. Note that the names of the module routines should be unique to that implementation in order to permit using more than one SUNNONLINSOL module (each with different SUNNonlinearSolver internal data representations) in the same code.
- 3. Define and implement a user-callable constructor to create a SUNNonlinearSolver object.

Additionally, a SUNNonlinearSolver implementation may do the following:

- 1. Define and implement additional user-callable "set" routines acting on the SUNNonlinearSolver object, e.g., for setting various configuration options to tune the performance of the nonlinear solve algorithm.
- 2. Provide additional user-callable "get" routines acting on the SUNNonlinearSolver object, e.g., for returning various solve statistics.

9.2 The SUNNonlinearSolver_Newton implementation

This section describes the SUNNONLINSOL implementation of Newton's method. To access the SUNNON-LINSOL_NEWTON module, include the header file sunnonlinsol/sunnonlinsol_newton.h. We note that the SUNNONLINSOL_NEWTON module is accessible from SUNDIALS integrators without separately linking to the libsundials_sunnonlinsolnewton module library.

9.2.1 SUNNonlinearSolver_Newton description

To find the solution to

$$F(y) = 0 (9.1)$$

given an initial guess $y^{(0)}$, Newton's method computes a series of approximate solutions

$$y^{(m+1)} = y^{(m)} + \delta^{(m+1)} \tag{9.2}$$

where m is the Newton iteration index, and the Newton update $\delta^{(m+1)}$ is the solution of the linear system

$$A(y^{(m)})\delta^{(m+1)} = -F(y^{(m)}), (9.3)$$

in which A is the Jacobian matrix

$$A \equiv \partial F/\partial y \,. \tag{9.4}$$

Depending on the linear solver used, the Sunnonlinsol_newton module will employ either a Modified Newton method, or an Inexact Newton method [4, 7, 15, 17, 30]. When used with a direct linear solver, the Jacobian matrix A is held constant during the Newton iteration, resulting in a Modified Newton method. With a matrix-free iterative linear solver, the iteration is an Inexact Newton method.

In both cases, calls to the integrator-supplied ${\tt SUNNonlinSollSetupFn}$ function are made infrequently to amortize the increased cost of matrix operations (updating A and its factorization within direct linear solvers, or updating the preconditioner within iterative linear solvers). Specifically, ${\tt SUNNonlinSollSetupFn}$ function in two instances:

- (a) when requested by the integrator (the input callLSetSetup is SUNTRUE) before attempting the Newton iteration, or
- (b) when reattempting the nonlinear solve after a recoverable failure occurs in the Newton iteration with stale Jacobian information (jcur is SUNFALSE). In this case, SUNNONLINSOL_NEWTON will set jbad to SUNTRUE before calling the SUNNonlinSollSetupFn function.

Whether the Jacobian matrix A is fully or partially updated depends on logic unique to each integrator-supplied SUNNonlinSolSetupFn routine. We refer to the discussion of nonlinear solver strategies provided in Chapter 2 for details on this decision.

The default maximum number of iterations and the stopping criteria for the Newton iteration are supplied by the SUNDIALS integrator when SUNNONLINSOL_NEWTON is attached to it. Both the maximum number of iterations and the convergence test function may be modified by the user by calling the SUNNonlinSolSetMaxIters and/or SUNNonlinSolSetConvTest functions after attaching the SUNNONLINSOL_NEWTON object to the integrator.

9.2.2 SUNNonlinearSolver_Newton functions

The SUNNONLINSOL_NEWTON module provides the following constructor for creating the SUNNonlinearSolver object.

SUNNonlinSol_Newton

Call NLS = SUNNonlinSol_Newton(y);

Description The function SUNNonlinSol_Newton creates a SUNNonlinearSolver object for use with SUNDIALS integrators to solve nonlinear systems of the form F(y) = 0 using Newton's method.

Arguments y (N_Vector) a template for cloning vectors needed within the solver.

Return value The return value NLS (of type SUNNonlinearSolver) will be a SUNNONLINSOL object if the constructor exits successfully, otherwise NLS will be NULL.

The SUNNONLINSOL_NEWTON module implements all of the functions defined in sections 9.1.1 - 9.1.3 except for the SUNNonlinSolSetup function. The SUNNONLINSOL_NEWTON functions have the same names as those defined by the generic SUNNONLINSOL API with _Newton appended to the function name. Unless using the SUNNONLINSOL_NEWTON module as a standalone nonlinear solver the generic functions defined in sections 9.1.1 - 9.1.3 should be called in favor of the SUNNONLINSOL_NEWTON-specific implementations.

The SUNNONLINSOL_NEWTON module also defines the following additional user-callable function.

```
|SUNNonlinSolGetSysFn_Newton
```

Call retval = SUNNonlinSolGetSysFn_Newton(NLS, SysFn);

Description The function SUNNonlinSolGetSysFn_Newton returns the residual function that defines

the nonlinear system.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object

SysFn (SUNNonlinSolSysFn*) the function defining the nonlinear system.

Return value The return value retval (of type int) should be zero for a successful call, and a negative

value for a failure.

Notes This function is intended for users that wish to evaluate the nonlinear residual in a

custom convergence test function for the SUNNONLINSOL_NEWTON module. We note that SUNNONLINSOL_NEWTON will not leverage the results from any user calls to SysFn.

9.2.3 SUNNonlinearSolver_Newton content

The content field of the SUNNONLINSOL_NEWTON module is the following structure.

```
struct _SUNNonlinearSolverContent_Newton {
  SUNNonlinSolSysFn
                          Sys;
  SUNNonlinSolLSetupFn
                          LSetup;
  SUNNonlinSolLSolveFn
                          LSolve;
  SUNNonlinSolConvTestFn CTest;
  N_Vector
              delta;
  booleantype jcur;
  int
              curiter;
  int
              maxiters;
  long int
              niters;
};
```

These entries of the *content* field contain the following information:

Sys - the function for evaluating the nonlinear system,

LSetup - the package-supplied function for setting up the linear solver,

LSolve - the package-supplied function for performing a linear solve,

CTest - the function for checking convergence of the Newton iteration,

delta - the Newton iteration update vector,

jcur - the Jacobian status (SUNTRUE = current, SUNFALSE = stale),

curiter - the current number of iterations in the solve attempt,

maxiters - the maximum number of Newton iterations allowed in a solve, and

niters - the total number of nonlinear iterations across all solves.

9.2.4 SUNNonlinearSolver_Newton Fortran interface

For SUNDIALS integrators that include a Fortran interface, the SUNNONLINSOL_NEWTON module also includes a Fortran-callable function for creating a SUNNonlinearSolver object.

FSUNNEWTONINIT

Description The function FSUNNEWTONINIT can be called for Fortran programs to create a SUNNonlinearSolver object for use with SUNDIALS integrators to solve nonlinear systems of the form F(y) = 0 with Newton's method.

Arguments code (int*) is an integer input specifying the solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, and 4 for ARKODE).

Return value ier is a return completion flag equal to 0 for a success return and -1 otherwise. See printed message for details in case of failure.

9.3 The SUNNonlinearSolver_FixedPoint implementation

This section describes the SUNNONLINSOL implementation of a fixed point (functional) iteration with optional Anderson acceleration. To access the SUNNONLINSOL_FIXEDPOINT module, include the header file sunnonlinsol/sunnonlinsol_fixedpoint.h. We note that the SUNNONLINSOL_FIXEDPOINT module is accessible from SUNDIALS integrators without separately linking to the libsundials_sunnonlinsolfixedpoint module library.

9.3.1 SUNNonlinearSolver_FixedPoint description

To find the solution to

$$G(y) = y (9.5)$$

given an initial guess $y^{(0)}$, the fixed point iteration computes a series of approximate solutions

$$y^{(n+1)} = G(y^{(n)}) (9.6)$$

where n is the iteration index. The convergence of this iteration may be accelerated using Anderson's method [3, 38, 18, 32]. With Anderson acceleration using subspace size m, the series of approximate solutions can be formulated as the linear combination

$$y^{(n+1)} = \sum_{i=0}^{m_n} \alpha_i^{(n)} G(y^{(n-m_n+i)})$$
(9.7)

where $m_n = \min\{m, n\}$ and the factors

$$\alpha^{(n)} = (\alpha_0^{(n)}, \dots, \alpha_{m_n}^{(n)}) \tag{9.8}$$

solve the minimization problem $\min_{\alpha} \|F_n \alpha^T\|_2$ under the constraint that $\sum_{i=0}^{m_n} \alpha_i = 1$ where

$$F_n = (f_{n-m_n}, \dots, f_n) \tag{9.9}$$

with $f_i = G(y^{(i)}) - y^{(i)}$. Due to this constraint, in the limit of m = 0 the accelerated fixed point iteration formula (9.7) simplifies to the standard fixed point iteration (9.6).

Following the recommendations made in [38], the SUNNONLINSOL_FIXEDPOINT implementation computes the series of approximate solutions as

$$y^{(n+1)} = G(y^{(n)}) - \sum_{i=0}^{m_n - 1} \gamma_i^{(n)} \Delta g_{n-m_n+i}$$
(9.10)

with $\Delta g_i = G(y^{(i+1)}) - G(y^{(i)})$ and where the factors

$$\gamma^{(n)} = (\gamma_0^{(n)}, \dots, \gamma_{m_n-1}^{(n)}) \tag{9.11}$$

solve the unconstrained minimization problem $\min_{\gamma} \|f_n - \Delta F_n \gamma^T\|_2$ where

$$\Delta F_n = (\Delta f_{n-m_n}, \dots, \Delta f_{n-1}), \tag{9.12}$$

with $\Delta f_i = f_{i+1} - f_i$. The least-squares problem is solved by applying a QR factorization to $\Delta F_n = Q_n R_n$ and solving $R_n \gamma = Q_n^T f_n$.

The acceleration subspace size m is required when constructing the SUNNONLINSOL_FIXEDPOINT object. The default maximum number of iterations and the stopping criteria for the fixed point iteration are supplied by the SUNDIALS integrator when SUNNONLINSOL_FIXEDPOINT is attached to it. Both the maximum number of iterations and the convergence test function may be modified by the user by calling SUNNonlinSolSetMaxIters and SUNNonlinSolSetConvTest functions after attaching the SUNNONLINSOL_FIXEDPOINT object to the integrator.

9.3.2 SUNNonlinearSolver FixedPoint functions

The SUNNONLINSOL_FIXEDPOINT module provides the following constructor for creating the SUNNonlinearSolver object.

SUNNonlinSol_FixedPoint

Call NLS = SUNNonlinSol_FixedPoint(y, m);

 $Description \quad The \ function \ {\tt SUNNonlinSol_FixedPoint} \ creates \ a \ {\tt SUNNonlinearSolver} \ object \ for \ use$

with SUNDIALS integrators to solve nonlinear systems of the form G(y) = y.

Arguments y (N_Vector) a template for cloning vectors needed within the solver

m (int) the number of acceleration vectors to use

Return value The return value NLS (of type SUNNonlinearSolver) will be a SUNNONLINSOL object if the constructor exits successfully, otherwise NLS will be NULL.

Since the accelerated fixed point iteration (9.6) does not require the setup or solution of any linear systems, the SUNNONLINSOL_FIXEDPOINT module implements all of the functions defined in sections 9.1.1 - 9.1.3 except for the SUNNonlinSolveSetup, SUNNonlinSolSetLSetupFn, and

SUNNonlinSolSetLSolveFn functions, that are set to NULL. The SUNNONLINSOL_FIXEDPOINT functions have the same names as those defined by the generic SUNNONLINSOL API with _FixedPoint appended to the function name. Unless using the SUNNONLINSOL_FIXEDPOINT module as a standalone nonlinear solver the generic functions defined in sections 9.1.1 - 9.1.3 should be called in favor of the SUNNONLINSOL_FIXEDPOINT-specific implementations.

The $SUNNONLINSOL_FIXEDPOINT$ module also defines the following additional user-callable function.

|SUNNonlinSolGetSysFn_FixedPoint

Call retval = SUNNonlinSolGetSysFn_FixedPoint(NLS, SysFn);

Description The function SUNNonlinSolGetSysFn_FixedPoint returns the fixed-point function that

defines the nonlinear system.

Arguments NLS (SUNNonlinearSolver) a SUNNONLINSOL object

SysFn (SUNNonlinSolSysFn*) the function defining the nonlinear system.

Return value The return value retval (of type int) should be zero for a successful call, and a negative

value for a failure.

Notes This function is intended for users that wish to evaluate the fixed-point function in a custom convergence test function for the SUNNONLINSOL_FIXEDPOINT module. We note

custom convergence test function for the SUNNONLINSOL_FIXEDPOINT module. We note that SUNNONLINSOL_FIXEDPOINT will not leverage the results from any user calls to

SysFn.

9.3.3 SUNNonlinearSolver FixedPoint content

The content field of the SUNNONLINSOL_FIXEDPOINT module is the following structure.

```
struct _SUNNonlinearSolverContent_FixedPoint {
  SUNNonlinSolSysFn
                             Sys;
  SUNNonlinSolConvTestFn CTest;
  int
             m;
  int
            *imap;
  realtype *R;
  realtype *gamma;
  realtype *cvals;
  N_Vector *df;
  N_Vector *dg;
  N_Vector *q;
  N_Vector *Xvecs;
  N_Vector yprev;
  N_Vector gy;
  N_Vector
             fold;
  N_Vector
             gold;
  N_Vector delta;
  int
             curiter;
  int
             maxiters;
  long int niters;
};
The following entries of the content field are always allocated:
          - function for evaluating the nonlinear system,
Sys
CTest
          - function for checking convergence of the fixed point iteration,
          - N_Vector used to store previous fixed-point iterate,
yprev
          - N_Vector used to store G(y) in fixed-point algorithm,
gу
          - N_Vector used to store difference between successive fixed-point iterates,
delta
curiter - the current number of iterations in the solve attempt,
maxiters - the maximum number of fixed-point iterations allowed in a solve, and
          - the total number of nonlinear iterations across all solves.
          - number of acceleration vectors,
If Anderson acceleration is requested (i.e., m > 0 in the call to SUNNonlinSol_FixedPoint), then the
following items are also allocated within the content field:
imap - index array used in acceleration algorithm (length m)
R
      - small matrix used in acceleration algorithm (length m*m)
gamma - small vector used in acceleration algorithm (length m)
cvals - small vector used in acceleration algorithm (length m+1)
df
      - array of N_Vectors used in acceleration algorithm (length m)
dg
      - array of N_Vectors used in acceleration algorithm (length m)
      - array of N_Vectors used in acceleration algorithm (length m)
Xvecs - N_Vector pointer array used in acceleration algorithm (length m+1)
fold - N_Vector used in acceleration algorithm
gold - N_Vector used in acceleration algorithm
```

9.3.4 SUNNonlinearSolver_FixedPoint Fortran interface

For SUNDIALS integrators that include a Fortran interface, the SUNNONLINSOL_FIXEDPOINT module also includes a Fortran-callable function for creating a SUNNonlinearSolver object.

FSUNFIXEDPOINTINIT

Call FSUNFIXEDPOINTINIT(code, m, ier);

Description The function FSUNFIXEDPOINTINIT can be called for Fortran programs to create a

SUNNonlinearSolver object for use with SUNDIALS integrators to solve nonlinear sys-

tems of the form G(y) = y.

Arguments code (int*) is an integer input specifying the solver id (1 for CVODE, 2 for IDA, 3 for

KINSOL, and 4 for ARKODE).

m (int*) is an integer input specifying the number of acceleration vectors.

Return value ier is a return completion flag equal to 0 for a success return and -1 otherwise. See

printed message for details in case of failure.

Appendix A

SUNDIALS Package Installation Procedure

The installation of any SUNDIALS package is accomplished by installing the SUNDIALS suite as a whole, according to the instructions that follow. The same procedure applies whether or not the downloaded file contains one or all solvers in SUNDIALS.

The SUNDIALS suite (or individual solvers) are distributed as compressed archives (.tar.gz). The name of the distribution archive is of the form *solver-x.y.z.tar.gz*, where *solver* is one of: sundials, cvode, cvodes, arkode, ida, idas, or kinsol, and x.y.z represents the version number (of the SUNDIALS suite or of the individual solver). To begin the installation, first uncompress and expand the sources, by issuing

% tar xzf solver-x.y.z.tar.gz

This will extract source files under a directory *solver*-x.y.z.

Starting with version 2.6.0 of SUNDIALS, CMake is the only supported method of installation. The explanations of the installation procedure begins with a few common observations:

• The remainder of this chapter will follow these conventions:

solverdir is the directory solver-x.y.z created above; i.e., the directory containing the SUNDI-ALS sources.

builddir is the (temporary) directory under which SUNDIALS is built.

instdir is the directory under which the SUNDIALS exported header files and libraries will be installed. Typically, header files are exported under a directory instdir/include while libraries are installed under instdir/lib, with instdir specified at configuration time.

- For sundials CMake-based installation, in-source builds are prohibited; in other words, the build directory *builddir* can **not** be the same as *solverdir* and such an attempt will lead to an error. This prevents "polluting" the source tree and allows efficient builds for different configurations and/or options.
- The installation directory instdir can **not** be the same as the source directory solverdir.
- By default, only the libraries and header files are exported to the installation directory *instdir*. If enabled by the user (with the appropriate toggle for CMake), the examples distributed with SUNDIALS will be built together with the solver libraries but the installation step will result in exporting (by default in a subdirectory of the installation directory) the example sources and sample outputs together with automatically generated configuration files that reference the *installed* SUNDIALS headers and libraries. As such, these configuration files for the SUNDIALS examples can be used as "templates" for your own problems. CMake installs CMakeLists.txt files and also (as an option available only under Unix/Linux) Makefile files. Note this installation

approach also allows the option of building the SUNDIALS examples without having to install them. (This can be used as a sanity check for the freshly built libraries.)

• Even if generation of shared libraries is enabled, only static libraries are created for the FCMIX modules. (Because of the use of fixed names for the Fortran user-provided subroutines, FCMIX shared libraries would result in "undefined symbol" errors at link time.)

A.1 CMake-based installation

CMake-based installation provides a platform-independent build system. CMake can generate Unix and Linux Makefiles, as well as KDevelop, Visual Studio, and (Apple) XCode project files from the same configuration file. In addition, CMake also provides a GUI front end and which allows an interactive build and installation process.

The SUNDIALS build process requires CMake version 3.0.2 or higher and a working C compiler. On Unix-like operating systems, it also requires Make (and curses, including its development libraries, for the GUI front end to CMake, ccmake), while on Windows it requires Visual Studio. While many Linux distributions offer CMake, the version included may be out of date. CMake is continually adding new features, and the latest version can be downloaded from http://www.cmake.org. Build instructions for CMake (only necessary for Unix-like systems) can be found on the CMake website. Once CMake is installed, Linux/Unix users will be able to use ccmake, while Windows users will be able to use CMakeSetup.

As previously noted, when using CMake to configure, build and install SUNDIALS, it is always required to use a separate build directory. While in-source builds are possible, they are explicitly prohibited by the SUNDIALS CMake scripts (one of the reasons being that, unlike autotools, CMake does not provide a make distclean procedure and it is therefore difficult to clean-up the source tree after an in-source build). By ensuring a separate build directory, it is an easy task for the user to clean-up all traces of the build by simply removing the build directory. CMake does generate a make clean which will remove files generated by the compiler and linker.

A.1.1 Configuring, building, and installing on Unix-like systems

The default CMake configuration will build all included solvers and associated examples and will build static and shared libraries. The *instdir* defaults to /usr/local and can be changed by setting the CMAKE_INSTALL_PREFIX variable. Support for FORTRAN and all other options are disabled.

CMake can be used from the command line with the cmake command, or from a curses-based GUI by using the ccmake command. Examples for using both methods will be presented. For the examples shown it is assumed that there is a top level SUNDIALS directory with appropriate source, build and install directories:

```
% mkdir (...)sundials/instdir
% mkdir (...)sundials/builddir
% cd (...)sundials/builddir
```

Building with the GUI

Using CMake with the GUI follows this general process:

- Select and modify values, run configure (c key)
- New values are denoted with an asterisk
- To set a variable, move the cursor to the variable and press enter
 - If it is a boolean (ON/OFF) it will toggle the value
 - If it is string or file, it will allow editing of the string

- For file and directories, the <tab> key can be used to complete
- Repeat until all values are set as desired and the generate option is available (g key)
- Some variables (advanced variables) are not visible right away
- To see advanced variables, toggle to advanced mode (t key)
- To search for a variable press / key, and to repeat the search, press the n key

To build the default configuration using the GUI, from the *builddir* enter the ccmake command and point to the *solverdir*:

% ccmake ../solverdir

The default configuration screen is shown in Figure A.1.

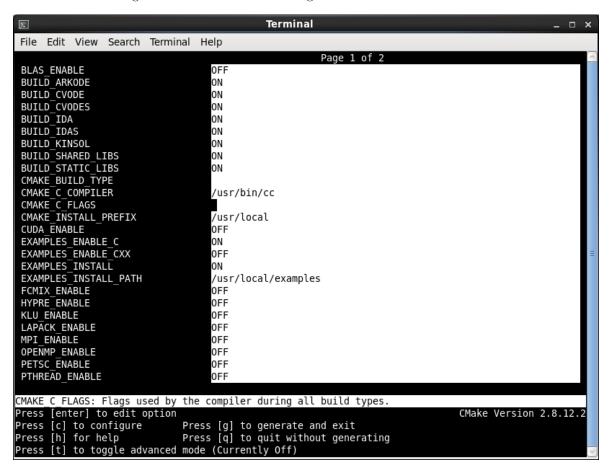

Figure A.1: Default configuration screen. Note: Initial screen is empty. To get this default configuration, press 'c' repeatedly (accepting default values denoted with asterisk) until the 'g' option is available.

The default *instdir* for both SUNDIALS and corresponding examples can be changed by setting the CMAKE_INSTALL_PREFIX and the EXAMPLES_INSTALL_PATH as shown in figure A.2.

Pressing the (g key) will generate makefiles including all dependencies and all rules to build SUNDIALS on this system. Back at the command prompt, you can now run:

% make

To install SUNDIALS in the installation directory specified in the configuration, simply run:

% make install

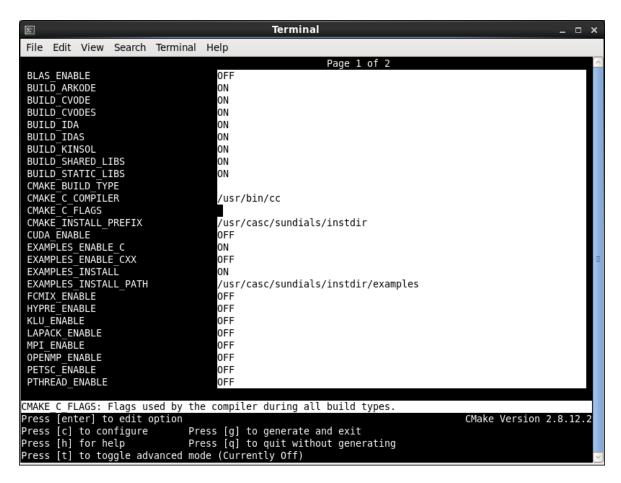

Figure A.2: Changing the *instdir* for SUNDIALS and corresponding examples

Building from the command line

Using CMake from the command line is simply a matter of specifying CMake variable settings with the cmake command. The following will build the default configuration:

```
% cmake -DCMAKE_INSTALL_PREFIX=/home/myname/sundials/instdir \
> -DEXAMPLES_INSTALL_PATH=/home/myname/sundials/instdir/examples \
> ../solverdir
% make
% make install
```

A.1.2 Configuration options (Unix/Linux)

A complete list of all available options for a CMake-based SUNDIALS configuration is provide below. Note that the default values shown are for a typical configuration on a Linux system and are provided as illustration only.

```
BLAS_ENABLE - Enable BLAS support
Default: OFF
```

Note: Setting this option to ON will trigger additional CMake options. See additional information on building with BLAS enabled in A.1.4.

```
BLAS_LIBRARIES - BLAS library
Default: /usr/lib/libblas.so
```

Note: CMake will search for libraries in your LD_LIBRARY_PATH prior to searching default system paths.

BUILD_ARKODE - Build the ARKODE library

Default: ON

BUILD_CVODE - Build the CVODE library

Default: ON

BUILD_CVODES - Build the CVODES library

Default: ON

BUILD_IDA - Build the IDA library

Default: ON

BUILD_IDAS - Build the IDAS library

Default: ON

BUILD_KINSOL - Build the KINSOL library

Default: ON

BUILD_SHARED_LIBS - Build shared libraries

Default: ON

BUILD_STATIC_LIBS - Build static libraries

Default: ON

CMAKE_BUILD_TYPE - Choose the type of build, options are: None (CMAKE_C_FLAGS used), Debug, Release, RelWithDebInfo, and MinSizeRel

Default:

Note: Specifying a build type will trigger the corresponding build type specific compiler flag options below which will be appended to the flags set by CMAKE_<language>_FLAGS.

 ${\tt CMAKE_C_COMPILER\ -\ C\ compiler}$

Default: /usr/bin/cc

CMAKE_C_FLAGS - Flags for C compiler

Default:

CMAKE_C_FLAGS_DEBUG - Flags used by the C compiler during debug builds

Default: -g

CMAKE_C_FLAGS_MINSIZEREL - Flags used by the C compiler during release minsize builds

Default: -Os -DNDEBUG

CMAKE_C_FLAGS_RELEASE - Flags used by the C compiler during release builds

Default: -O3 -DNDEBUG

CMAKE_CXX_COMPILER - C++ compiler

Default: /usr/bin/c++

Note: A C++ compiler (and all related options) are only triggered if C++ examples are enabled (EXAMPLES_ENABLE_CXX is ON). All SUNDIALS solvers can be used from C++ applications by default without setting any additional configuration options.

CMAKE_CXX_FLAGS - Flags for C++ compiler

Default:

CMAKE_CXX_FLAGS_DEBUG - Flags used by the C++ compiler during debug builds

Default: -g

 $\label{eq:cmake_cxx_flags_minsize} \textbf{CMAKE_CXX_FLAGS_MINSIZEREL} \ - \ Flags \ used \ by \ the \ C^{++} \ compiler \ during \ release \ minsize \ builds \\ Default: \ -Os \ -DNDEBUG$

 $\label{eq:cmake_cxx_flags_release} \textbf{CMAKE_CXX_FLAGS_RELEASE} \ - \ Flags \ used \ by \ the \ C^{++} \ compiler \ during \ release \ builds \\ Default: \ -O3 \ -DNDEBUG$

CMAKE_Fortran_COMPILER - Fortran compiler

Default: /usr/bin/gfortran

Note: Fortran support (and all related options) are triggered only if either Fortran-C support is enabled (FCMIX_ENABLE is ON) or BLAS/LAPACK support is enabled (BLAS_ENABLE or LAPACK_ENABLE is ON).

${\tt CMAKE_Fortran_FLAGS} \ - \ {\tt Flags} \ \ {\tt for} \ \ {\tt Fortran} \ \ {\tt compiler}$

Default:

CMAKE_Fortran_FLAGS_MINSIZEREL - Flags used by the Fortran compiler during release minsize builds Default: -Os

CMAKE_Fortran_FLAGS_RELEASE - Flags used by the Fortran compiler during release builds Default: -O3

CMAKE_INSTALL_PREFIX - Install path prefix, prepended onto install directories

Default: /usr/local

Note: The user must have write access to the location specified through this option. Exported SUNDIALS header files and libraries will be installed under subdirectories include and lib of CMAKE_INSTALL_PREFIX, respectively.

CUDA_ENABLE - Build the SUNDIALS CUDA vector module.

Default: OFF

EXAMPLES_ENABLE_C - Build the SUNDIALS C examples

Default: ON

EXAMPLES_ENABLE_CUDA - Build the SUNDIALS CUDA examples

Default: OFF

Note: You need to enable CUDA support to build these examples.

EXAMPLES_ENABLE_CXX - Build the SUNDIALS C++ examples

Default: OFF

EXAMPLES_ENABLE_RAJA - Build the SUNDIALS RAJA examples

Default: OFF

Note: You need to enable CUDA and RAJA support to build these examples.

EXAMPLES_ENABLE_F77 - Build the SUNDIALS Fortran77 examples

Default: ON (if FCMIX_ENABLE is ON)

EXAMPLES_ENABLE_F90 - Build the SUNDIALS Fortran90 examples

Default: OFF

${\tt EXAMPLES_INSTALL~Install~example~files}$

Default: ON

Note: This option is triggered when any of the Sundials example programs are enabled (EXAMPLES_ENABLE_<language> is ON). If the user requires installation of example programs then the sources and sample output files for all Sundials modules that are currently enabled will be exported to the directory specified by EXAMPLES_INSTALL_PATH. A CMake configuration

script will also be automatically generated and exported to the same directory. Additionally, if the configuration is done under a Unix-like system, makefiles for the compilation of the example programs (using the installed SUNDIALS libraries) will be automatically generated and exported to the directory specified by EXAMPLES_INSTALL_PATH.

EXAMPLES_INSTALL_PATH - Output directory for installing example files

Default: /usr/local/examples

Note: The actual default value for this option will be an examples subdirectory created under CMAKE_INSTALL_PREFIX.

FCMIX_ENABLE - Enable Fortran-C support

Default: OFF

HYPRE_ENABLE - Enable hypre support

Default: OFF

Note: See additional information on building with hypre enabled in A.1.4.

 ${\tt HYPRE_INCLUDE_DIR - Path \ to} \ hypre \ {\tt header \ files}$

HYPRE_LIBRARY_DIR - Path to hypre installed library files

KLU_ENABLE - Enable KLU support

Default: OFF

Note: See additional information on building with KLU enabled in A.1.4.

KLU_INCLUDE_DIR - Path to SuiteSparse header files

KLU_LIBRARY_DIR - Path to SuiteSparse installed library files

LAPACK_ENABLE - Enable LAPACK support

Default: OFF

Note: Setting this option to ON will trigger additional CMake options. See additional information on building with LAPACK enabled in A.1.4.

LAPACK_LIBRARIES - LAPACK (and BLAS) libraries

Default: /usr/lib/liblapack.so;/usr/lib/libblas.so

Note: CMake will search for libraries in your LD_LIBRARY_PATH prior to searching default system paths.

MPI_ENABLE - Enable MPI support (build the parallel nvector).

Default: OFF

Note: Setting this option to ON will trigger several additional options related to MPI.

MPI_C_COMPILER - mpicc program

Default:

MPI_CXX_COMPILER - mpicxx program

Default:

Note: This option is triggered only if MPI is enabled (MPI_ENABLE is ON) and C++ examples are enabled (EXAMPLES_ENABLE_CXX is ON). All SUNDIALS solvers can be used from C++ MPI applications by default without setting any additional configuration options other than MPI_ENABLE.

MPI_Fortran_COMPILER - mpif77 or mpif90 program

Default:

Note: This option is triggered only if MPI is enabled (MPI_ENABLE is ON), Fortran-C support is enabled (FCMIX_ENABLE is ON), and Fortran77 or Fortran90 examples are enabled (EXAMPLES_ENABLE_F77 or EXAMPLES_ENABLE_F90 are ON).

MPIEXEC_EXECUTABLE - Specify the executable for running MPI programs

Default: mpirun

Note: This option is triggered only if MPI is enabled (MPI_ENABLE is ON).

OPENMP_ENABLE - Enable OpenMP support (build the OpenMP nvector).

Default: OFF

PETSC_ENABLE - Enable PETSc support

Default: OFF

Note: See additional information on building with PETSc enabled in A.1.4.

PETSC_INCLUDE_DIR - Path to PETSc header files

PETSC_LIBRARY_DIR - Path to PETSc installed library files

PTHREAD_ENABLE - Enable Pthreads support (build the Pthreads nvector).

Default: OFF

RAJA_ENABLE - Enable RAJA support (build the RAJA nvector).

Default: OFF

Note: You need to enable CUDA in order to build the RAJA vector module.

SUNDIALS_F77_FUNC_CASE - advanced option - Specify the case to use in the Fortran name-mangling scheme, options are: lower or upper

Default:

Note: The build system will attempt to infer the Fortran name-mangling scheme using the Fortran compiler. This option should only be used if a Fortran compiler is not available or to override the inferred or default (lower) scheme if one can not be determined. If used, SUNDIALS_F77_FUNC_UNDERSCORES must also be set.

SUNDIALS_F77_FUNC_UNDERSCORES - advanced option - Specify the number of underscores to append in the Fortran name-mangling scheme, options are: none, one, or two Default:

Note: The build system will attempt to infer the Fortran name-mangling scheme using the Fortran compiler. This option should only be used if a Fortran compiler is not available or to override the inferred or default (one) scheme if one can not be determined. If used, SUNDIALS_F77_FUNC_CASE must also be set.

SUNDIALS_INDEX_TYPE - Integer type used for SUNDIALS indices, options are: int32_t or int64_t

Default: int64_t

SUNDIALS_PRECISION - Precision used in SUNDIALS, options are: double, single, or extended Default: double

 ${\tt SUPERLUMT_ENABLE}$ - Enable SuperLU_MT support

Default: OFF

Note: See additional information on building with SuperLU_MT enabled in A.1.4.

SUPERLUMT_INCLUDE_DIR - Path to SuperLU_MT header files (typically SRC directory)

SUPERLUMT_LIBRARY_DIR - Path to SuperLU_MT installed library files

SUPERLUMT_THREAD_TYPE - Must be set to Pthread or OpenMP

Default: Pthread

USE_GENERIC_MATH - Use generic (stdc) math libraries

Default: ON

xSDK Configuration Options

SUNDIALS supports CMake configuration options defined by the Extreme-scale Scientific Software Development Kit (xSDK) community policies (see https://xsdk.info for more information). xSDK CMake options are unused by default but may be activated by setting USE_XSDK_DEFAULTS to ON.

When xSDK options are active, they will overwrite the corresponding SUNDIALS option and may have different default values (see details below). As such the equivalent SUNDIALS options should not be used when configuring with xSDK options. In the GUI front end to CMake (ccmake), setting USE_XSDK_DEFAULTS to ON will hide the corresponding SUNDIALS options as advanced CMake variables. During configuration, messages are output detailing which xSDK flags are active and the equivalent SUNDIALS options that are replaced. Below is a complete list xSDK options and the corresponding SUNDIALS options if applicable.

TPL_BLAS_LIBRARIES - BLAS library

Default: /usr/lib/libblas.so

SUNDIALS equivalent: BLAS_LIBRARIES

Note: CMake will search for libraries in your LD_LIBRARY_PATH prior to searching default system

paths.

TPL_ENABLE_BLAS - Enable BLAS support

Default: OFF

SUNDIALS equivalent: BLAS_ENABLE

TPL_ENABLE_HYPRE - Enable hypre support

Default: OFF

SUNDIALS equivalent: HYPRE_ENABLE

${\tt TPL_ENABLE_KLU~-~Enable~KLU~support}$

Default: OFF

SUNDIALS equivalent: KLU_ENABLE

TPL_ENABLE_PETSC - Enable PETSc support

Default: OFF

SUNDIALS equivalent: PETSC_ENABLE

TPL_ENABLE_LAPACK - Enable LAPACK support

Default: OFF

SUNDIALS equivalent: LAPACK_ENABLE

TPL_ENABLE_SUPERLUMT - Enable SuperLU_MT support

Default: OFF

SUNDIALS equivalent: SUPERLUMT_ENABLE

TPL_HYPRE_INCLUDE_DIRS - Path to hypre header files

 ${\tt SUNDIALS\ equivalent:\ HYPRE_INCLUDE_DIR}$

${\tt TPL_HYPRE_LIBRARIES} \ - \ hypre \ {\tt library}$

SUNDIALS equivalent: N/A

TPL_KLU_INCLUDE_DIRS - Path to KLU header files

SUNDIALS equivalent: KLU_INCLUDE_DIR

TPL_KLU_LIBRARIES - KLU library

SUNDIALS equivalent: N/A

TPL_LAPACK_LIBRARIES - LAPACK (and BLAS) libraries

Default: /usr/lib/liblapack.so;/usr/lib/libblas.so

SUNDIALS equivalent: LAPACK_LIBRARIES

Note: CMake will search for libraries in your LD_LIBRARY_PATH prior to searching default system paths.

```
TPL_PETSC_INCLUDE_DIRS - Path to PETSc header files
     SUNDIALS equivalent: PETSC_INCLUDE_DIR
TPL_PETSC_LIBRARIES - PETSc library
     SUNDIALS equivalent: N/A
TPL_SUPERLUMT_INCLUDE_DIRS - Path to SuperLU_MT header files
     SUNDIALS equivalent: SUPERLUMT_INCLUDE_DIR
TPL_SUPERLUMT_LIBRARIES - SuperLU_MT library
     SUNDIALS equivalent: N/A
TPL_SUPERLUMT_THREAD_TYPE - SuperLU_MT library thread type
     SUNDIALS equivalent: SUPERLUMT_THREAD_TYPE
USE_XSDK_DEFAULTS - Enable xSDK default configuration settings
     Default: OFF
     SUNDIALS equivalent: N/A
     Note: Enabling xSDK defaults also sets CMAKE_BUILD_TYPE to Debug
XSDK_ENABLE_FORTRAN - Enable SUNDIALS Fortran interface
     Default: OFF
     SUNDIALS equivalent: FCMIX_ENABLE
XSDK_INDEX_SIZE - Integer size (bits) used for indices in SUNDIALS, options are: 32 or 64
     Default: 32
     SUNDIALS equivalent: SUNDIALS_INDEX_TYPE
XSDK_PRECISION - Precision used in SUNDIALS, options are: double, single, or quad
     Default: double
     SUNDIALS equivalent: SUNDIALS_PRECISION
```

A.1.3 Configuration examples

The following examples will help demonstrate usage of the CMake configure options.

To configure SUNDIALS using the default C and Fortran compilers, and default mpic and mpif77 parallel compilers, enable compilation of examples, and install libraries, headers, and example sources under subdirectories of /home/myname/sundials/, use:

```
% cmake \
> -DCMAKE_INSTALL_PREFIX=/home/myname/sundials/instdir \
> -DEXAMPLES_INSTALL_PATH=/home/myname/sundials/instdir/examples \
> -DMPI_ENABLE=ON \
> -DFCMIX_ENABLE=ON \
> /home/myname/sundials/solverdir
%
% make install
%

To disable installation of the examples, use:
% cmake \
> -DCMAKE_INSTALL_PREFIX=/home/myname/sundials/instdir \
> -DEXAMPLES_INSTALL_PATH=/home/myname/sundials/instdir/examples \
> -DMPI_ENABLE=ON \
```

- > -DFCMIX_ENABLE=ON \
- > -DEXAMPLES_INSTALL=OFF \
- > /home/myname/sundials/solverdir

```
%
% make install
%
```

A.1.4 Working with external Libraries

The SUNDIALS suite contains many options to enable implementation flexibility when developing solutions. The following are some notes addressing specific configurations when using the supported third party libraries. When building SUNDIALS as a shared library external libraries any used with SUNDIALS must also be build as a shared library or as a static library compiled with the -fPIC flag.

A

Building with BLAS

SUNDIALS does not utilize BLAS directly but it may be needed by other external libraries that SUNDIALS can be built with (e.g. LAPACK, PETSc, SuperLU_MT, etc.). To enable BLAS, set the BLAS_ENABLE option to ON. If the directory containing the BLAS library is in the LD_LIBRARY_PATH environment variable, CMake will set the BLAS_LIBRARIES variable accordingly, otherwise CMake will attempt to find the BLAS library in standard system locations. To explicitly tell CMake what libraries to use, the BLAS_LIBRARIES variable can be set to the desired library. Example:

```
% cmake \
> -DCMAKE_INSTALL_PREFIX=/home/myname/sundials/instdir \
> -DEXAMPLES_INSTALL_PATH=/home/myname/sundials/instdir/examples \
> -DBLAS_ENABLE=ON \
> -DBLAS_LIBRARIES=/myblaspath/lib/libblas.so \
> -DSUPERLUMT_ENABLE=ON \
> -DSUPERLUMT_INCLUDE_DIR=/mysuperlumtpath/SRC
> -DSUPERLUMT_LIBRARY_DIR=/mysuperlumtpath/lib
> /home/myname/sundials/solverdir
%
% make install
%
```

When allowing CMake to automatically locate the LAPACK library, CMake may also locate the corresponding BLAS library.

If a working Fortran compiler is not available to infer the Fortran name-mangling scheme, the options SUNDIALS_F77_FUNC_CASE and SUNDIALS_F77_FUNC_UNDERSCORES must be set in order to bypass the check for a Fortran compiler and define the name-mangling scheme. The defaults for these options in earlier versions of SUNDIALS were lower and one respectively.

Building with LAPACK

To enable LAPACK, set the LAPACK_ENABLE option to ON. If the directory containing the LAPACK library is in the LD_LIBRARY_PATH environment variable, CMake will set the LAPACK_LIBRARIES variable accordingly, otherwise CMake will attempt to find the LAPACK library in standard system locations. To explicitly tell CMake what library to use, the LAPACK_LIBRARIES variable can be set to the desired libraries. When setting the LAPACK location explicitly the location of the corresponding BLAS library will also need to be set. Example:

```
\triangle
```

```
% cmake \
> -DCMAKE_INSTALL_PREFIX=/home/myname/sundials/instdir \
> -DEXAMPLES_INSTALL_PATH=/home/myname/sundials/instdir/examples \
> -DBLAS_ENABLE=ON \
> -DBLAS_LIBRARIES=/mylapackpath/lib/libblas.so \
> -DLAPACK_ENABLE=ON \
> -DLAPACK_LIBRARIES=/mylapackpath/lib/liblapack.so \
```

```
> /home/myname/sundials/solverdir
%
% make install
%
```

When allowing CMake to automatically locate the LAPACK library, CMake may also locate the corresponding BLAS library.

If a working Fortran compiler is not available to infer the Fortran name-mangling scheme, the options SUNDIALS_F77_FUNC_CASE and SUNDIALS_F77_FUNC_UNDERSCORES must be set in order to bypass the check for a Fortran compiler and define the name-mangling scheme. The defaults for these options in earlier versions of SUNDIALS were lower and one respectively.

Building with KLU

The KLU libraries are part of SuiteSparse, a suite of sparse matrix software, available from the Texas A&M University website: http://faculty.cse.tamu.edu/davis/suitesparse.html. SUNDIALS has been tested with SuiteSparse version 4.5.3. To enable KLU, set KLU_ENABLE to ON, set KLU_INCLUDE_DIR to the include path of the KLU installation and set KLU_LIBRARY_DIR to the lib path of the KLU installation. The CMake configure will result in populating the following variables: AMD_LIBRARY, AMD_LIBRARY_DIR, BTF_LIBRARY_DIR, COLAMD_LIBRARY, COLAMD_LIBRARY_DIR, and KLU_LIBRARY.

Building with SuperLU_MT

The SuperLU_MT libraries are available for download from the Lawrence Berkeley National Laboratory website: http://crd-legacy.lbl.gov/~xiaoye/SuperLU/#superlu_mt. SUNDIALS has been tested with SuperLU_MT version 3.1. To enable SuperLU_MT, set SUPERLUMT_ENABLE to ON, set SUPERLUMT_INCLUDE_DIR to the SRC path of the SuperLU_MT installation, and set the variable SUPERLUMT_LIBRARY_DIR to the lib path of the SuperLU_MT installation. At the same time, the variable SUPERLUMT_THREAD_TYPE must be set to either Pthread or OpenMP.

Do not mix thread types when building SUNDIALS solvers. If threading is enabled for SUNDIALS by having either OPENMP_ENABLE or PTHREAD_ENABLE set to ON then SuperLU_MT should be set to use the same threading type.

Building with PETSc

The PETSc libraries are available for download from the Argonne National Laboratory website: http://www.mcs.anl.gov/petsc. SUNDIALS has been tested with PETSc version 3.7.2. To enable PETSc, set PETSC_ENABLE to ON, set PETSC_INCLUDE_DIR to the include path of the PETSc installation, and set the variable PETSC_LIBRARY_DIR to the lib path of the PETSc installation.

Building with hypre

The hypre libraries are available for download from the Lawrence Livermore National Laboratory website: http://computation.llnl.gov/projects/hypre. SUNDIALS has been tested with hypre version 2.11.1. To enable hypre, set HYPRE_ENABLE to ON, set HYPRE_INCLUDE_DIR to the include path of the hypre installation, and set the variable HYPRE_LIBRARY_DIR to the lib path of the hypre installation.

Building with CUDA

SUNDIALS CUDA modules and examples have been tested with version 8.0 of the CUDA toolkit. To build them, you need to install the Toolkit and compatible NVIDIA drivers. Both are available for download from the NVIDIA website: https://developer.nvidia.com/cuda-downloads. To enable CUDA, set CUDA_ENABLE to ON. If CUDA is installed in a nonstandard location, you may be prompted to

set the variable CUDA_TOOLKIT_ROOT_DIR with your CUDA Toolkit installation path. To enable CUDA examples, set EXAMPLES_ENABLE_CUDA to ON.

Building with RAJA

RAJA is a performance portability layer developed by Lawrence Livermore National Laboratory and can be obtained from https://github.com/LLNL/RAJA. SUNDIALS RAJA modules and examples have been tested with RAJA version 0.3. Building SUNDIALS RAJA modules requires a CUDA-enabled RAJA installation. To enable RAJA, set CUDA_ENABLE and RAJA_ENABLE to ON. If RAJA is installed in a nonstandard location you will be prompted to set the variable RAJA_DIR with the path to the RAJA CMake configuration file. To enable building the RAJA examples set EXAMPLES_ENABLE_RAJA to ON.

A.1.5 Testing the build and installation

If SUNDIALS was configured with EXAMPLES_ENABLE_<language> options to ON, then a set of regression tests can be run after building with the make command by running:

% make test

Additionally, if EXAMPLES_INSTALL was also set to ON, then a set of smoke tests can be run after installing with the make install command by running:

% make test_install

A.2 Building and Running Examples

Each of the SUNDIALS solvers is distributed with a set of examples demonstrating basic usage. To build and install the examples, set at least of the EXAMPLES_ENABLE_<language> options to ON, and set EXAMPLES_INSTALL to ON. Specify the installation path for the examples with the variable EXAMPLES_INSTALL_PATH. CMake will generate CMakeLists.txt configuration files (and Makefile files if on Linux/Unix) that reference the *installed* SUNDIALS headers and libraries.

Either the CMakeLists.txt file or the traditional Makefile may be used to build the examples as well as serve as a template for creating user developed solutions. To use the supplied Makefile simply run make to compile and generate the executables. To use CMake from within the installed example directory, run cmake (or ccmake to use the GUI) followed by make to compile the example code. Note that if CMake is used, it will overwrite the traditional Makefile with a new CMake-generated Makefile. The resulting output from running the examples can be compared with example output bundled in the SUNDIALS distribution.

NOTE: There will potentially be differences in the output due to machine architecture, compiler versions, use of third party libraries etc.

A.3 Configuring, building, and installing on Windows

CMake can also be used to build SUNDIALS on Windows. To build SUNDIALS for use with Visual Studio the following steps should be performed:

- 1. Unzip the downloaded tar file(s) into a directory. This will be the solverdir
- 2. Create a separate builddir
- 3. Open a Visual Studio Command Prompt and cd to builddir
- 4. Run cmake-gui ../solverdir
 - (a) Hit Configure
 - (b) Check/Uncheck solvers to be built

- (c) Change CMAKE_INSTALL_PREFIX to instdir
- (d) Set other options as desired
- (e) Hit Generate
- 5. Back in the VS Command Window:
 - (a) Run msbuild ALL_BUILD.vcxproj
 - (b) Run msbuild INSTALL.vcxproj

The resulting libraries will be in the *instdir*. The SUNDIALS project can also now be opened in Visual Studio. Double click on the ALL_BUILD.vcxproj file to open the project. Build the whole *solution* to create the SUNDIALS libraries. To use the SUNDIALS libraries in your own projects, you must set the include directories for your project, add the SUNDIALS libraries to your project solution, and set the SUNDIALS libraries as dependencies for your project.

A.4 Installed libraries and exported header files

Using the CMake SUNDIALS build system, the command

% make install

will install the libraries under *libdir* and the public header files under *includedir*. The values for these directories are *instdir*/lib and *instdir*/include, respectively. The location can be changed by setting the CMake variable CMAKE_INSTALL_PREFIX. Although all installed libraries reside under *libdir*/lib, the public header files are further organized into subdirectories under *includedir*/include.

The installed libraries and exported header files are listed for reference in Table A.1. The file extension .lib is typically .so for shared libraries and .a for static libraries. Note that, in the Tables, names are relative to libdir for libraries and to includedir for header files.

A typical user program need not explicitly include any of the shared SUNDIALS header files from under the <code>includedir/include/sundials</code> directory since they are explicitly included by the appropriate solver header files (e.g., <code>cvode_dense.h</code> includes <code>sundials_dense.h</code>). However, it is both legal and safe to do so, and would be useful, for example, if the functions declared in <code>sundials_dense.h</code> are to be used in building a preconditioner.

Table A.1: SUNDIALS libraries and header files

SHARED	Libraries	n/a	
	Header files	sundials/sundials_config.h	
		sundials/sundials_fconfig.h	
		sundials/sundials_types.h

Appendix B

CVODE Constants

Below we list all input and output constants used by the main solver and linear solver modules, together with their numerical values and a short description of their meaning.

B.1 CVODE input constants

	CV	ODE main solver module
CV_ADAMS	1	Adams-Moulton linear multistep method.
CV_BDF	2	BDF linear multistep method.
CV_NORMAL	1	Solver returns at specified output time.
CV_ONE_STEP	2	Solver returns after each successful step.
	Iter	ative linear solver module
PREC_NONE	0	No preconditioning
PREC_LEFT	1	Preconditioning on the left only.
PREC_RIGHT	2	Preconditioning on the right only.
PREC_BOTH	3	Preconditioning on both the left and the right.
$\mathtt{MODIFIED_GS}$	1	Use modified Gram-Schmidt procedure.
CLASSICAL_GS	2	Use classical Gram-Schmidt procedure.

B.2 CVODE output constants

CVODE main solver module		
CV_SUCCESS	0	Successful function return.
CV_TSTOP_RETURN	1	CVode succeeded by reaching the specified stopping point.
CV_ROOT_RETURN	2	CVode succeeded and found one or more roots.
CV_WARNING	99	CVode succeeded but an unusual situation occurred.
CV_TOO_MUCH_WORK	-1	The solver took mxstep internal steps but could not reach tout.
CV_TOO_MUCH_ACC	-2	The solver could not satisfy the accuracy demanded by the user for some internal step.

218 CVODE Constants

CV_ERR_FAILURE	-3	Error test failures occurred too many times during one internal time step or minimum step size was reached.
CV_CONV_FAILURE	-4	Convergence test failures occurred too many times during
ON LINET PAIL	E	one internal time step or minimum step size was reached. The linear solver's initialization function failed.
CV_LINIT_FAIL	-5	
CV_LSETUP_FAIL	-6	The linear solver's setup function failed in an unrecoverable
ON LOOLNE EATI	7	manner.
CV_LSOLVE_FAIL	-7	The linear solver's solve function failed in an unrecoverable manner.
CV_RHSFUNC_FAIL	-8	The right-hand side function failed in an unrecoverable man-
CV_RHSFUNC_FAIL	-0	ner.
CV_FIRST_RHSFUNC_ERR	-9	The right-hand side function failed at the first call.
CV_REPTD_RHSFUNC_ERR	-10	The right-hand side function had repeted recoverable er-
CV_REFID_RHSFUNC_ERR	-10	rors.
CV_UNREC_RHSFUNC_ERR	-11	The right-hand side function had a recoverable error, but no
01_011120_111161 0110_21141		recovery is possible.
CV_RTFUNC_FAIL	-12	The rootfinding function failed in an unrecoverable manner.
CV_MEM_FAIL	-20	A memory allocation failed.
CV_MEM_NULL	-21	The cvode_mem argument was NULL.
CV_ILL_INPUT	-22	One of the function inputs is illegal.
CV_NO_MALLOC	-23	The CVODE memory block was not allocated by a call to
01202	20	CVodeMalloc.
CV_BAD_K	-24	The derivative order k is larger than the order used.
CV_BAD_T	-25	The time t is outside the last step taken.
CV_BAD_DKY	-26	The output derivative vector is NULL.
CV_TOO_CLOSE	-27	The output and initial times are too close to each other.
0.1001020	_,	The eurplication and three cases are the early state.
	CVI	DLS linear solver modules
CVDLS_SUCCESS	0	Successful function return.
CVDLS_MEM_NULL	-1	The cvode_mem argument was NULL.
CVDLS_LMEM_NULL	-2	The CVDLS linear solver has not been initialized.
CVDLS_ILL_INPUT	-3	The CVDLS solver is not compatible with the current NVEC-
		TOR module.
CVDLS_MEM_FAIL	-4	A memory allocation request failed.
CVDLS_JACFUNC_UNRECVR	-5	The Jacobian function failed in an unrecoverable manner.
CVDLS_JACFUNC_RECVR	-6	The Jacobian function had a recoverable error.
CVDLS_SUNMAT_FAIL	-7	An error occurred with the current Sunmatrix module.
	CVI	DIAG linear solver module
CVDIAG_SUCCESS	0	Successful function return.
CVDIAG_MEM_NULL	-1	The cvode_mem argument was NULL.
CVDIAG_LMEM_NULL	-2	The CVDIAG linear solver has not been initialized.
CVDIAG_ILL_INPUT	-3	The CVDIAG solver is not compatible with the current NVEC-
		TOR module.

CVSPILS_MEM_FAIL

CVSPILS_PMEM_NULL

CVSPILS_SUNLS_FAIL

CVDIAG_MEM_FAIL	-4	A memory allocation request failed.
CVDIAG_INV_FAIL	-5	A diagonal element of the Jacobian was 0.
CVDIAG_RHSFUNC_UNRECVR	-6	The right-hand side function failed in an unrecoverable manner.
CVDIAG_RHSFUNC_RECVR	-7	The right-hand side function had a recoverable error.
	CVS	PILS linear solver modules
QUADTI A QUADTA		
CVSPILS_SUCCESS	0	Successful function return.
CVSPILS_SUCCESS CVSPILS_MEM_NULL		
*****	0	Successful function return.

-4

-5 -6 TOR module, or an input value was illegal. A memory allocation request failed.

The preconditioner module has not been initialized.

An error occurred with the current Sunlinsol module.
